## INTRODUCTION

### Purpose And Scope

The intent of this study is to provide a comprehensive presentation and **corresponding** analysis of available and pertinent **information** in reference to the North Fork **Mattole** River Watershed. The analysis of this watershed is presented with no predetermined land management objective in mind. Rather, it is intended that the compiled information will be of use to anyone interested in applying specific land management objectives to a given portion of the watershed. Thus, any current or prospective manager and user of the natural resources of the watershed will find that useful information can be gleaned from this report in relation to his present or future land management objectives and uses.

The analysis will be presented in six portions: physiographic, **socio-economic**, general problems, potentials of the area, resource summary, and conclusions. Because of the availability of certain information and the author's experience and interest, a major devotion of effort in the watershed analysis will be physiographic in nature. However, a consideration and discussion of certain other characteristics of the **area**, such as history, **problems**, and biotic aspects that play an instrumental role in evaluating the feasibility and consequences of land-use activity, **will be more** than superficial in the analysis.

## PART I

### PHYSIOGRAPHIC (TOPOGRAPHIC) ANALYSIS

#### Introduction

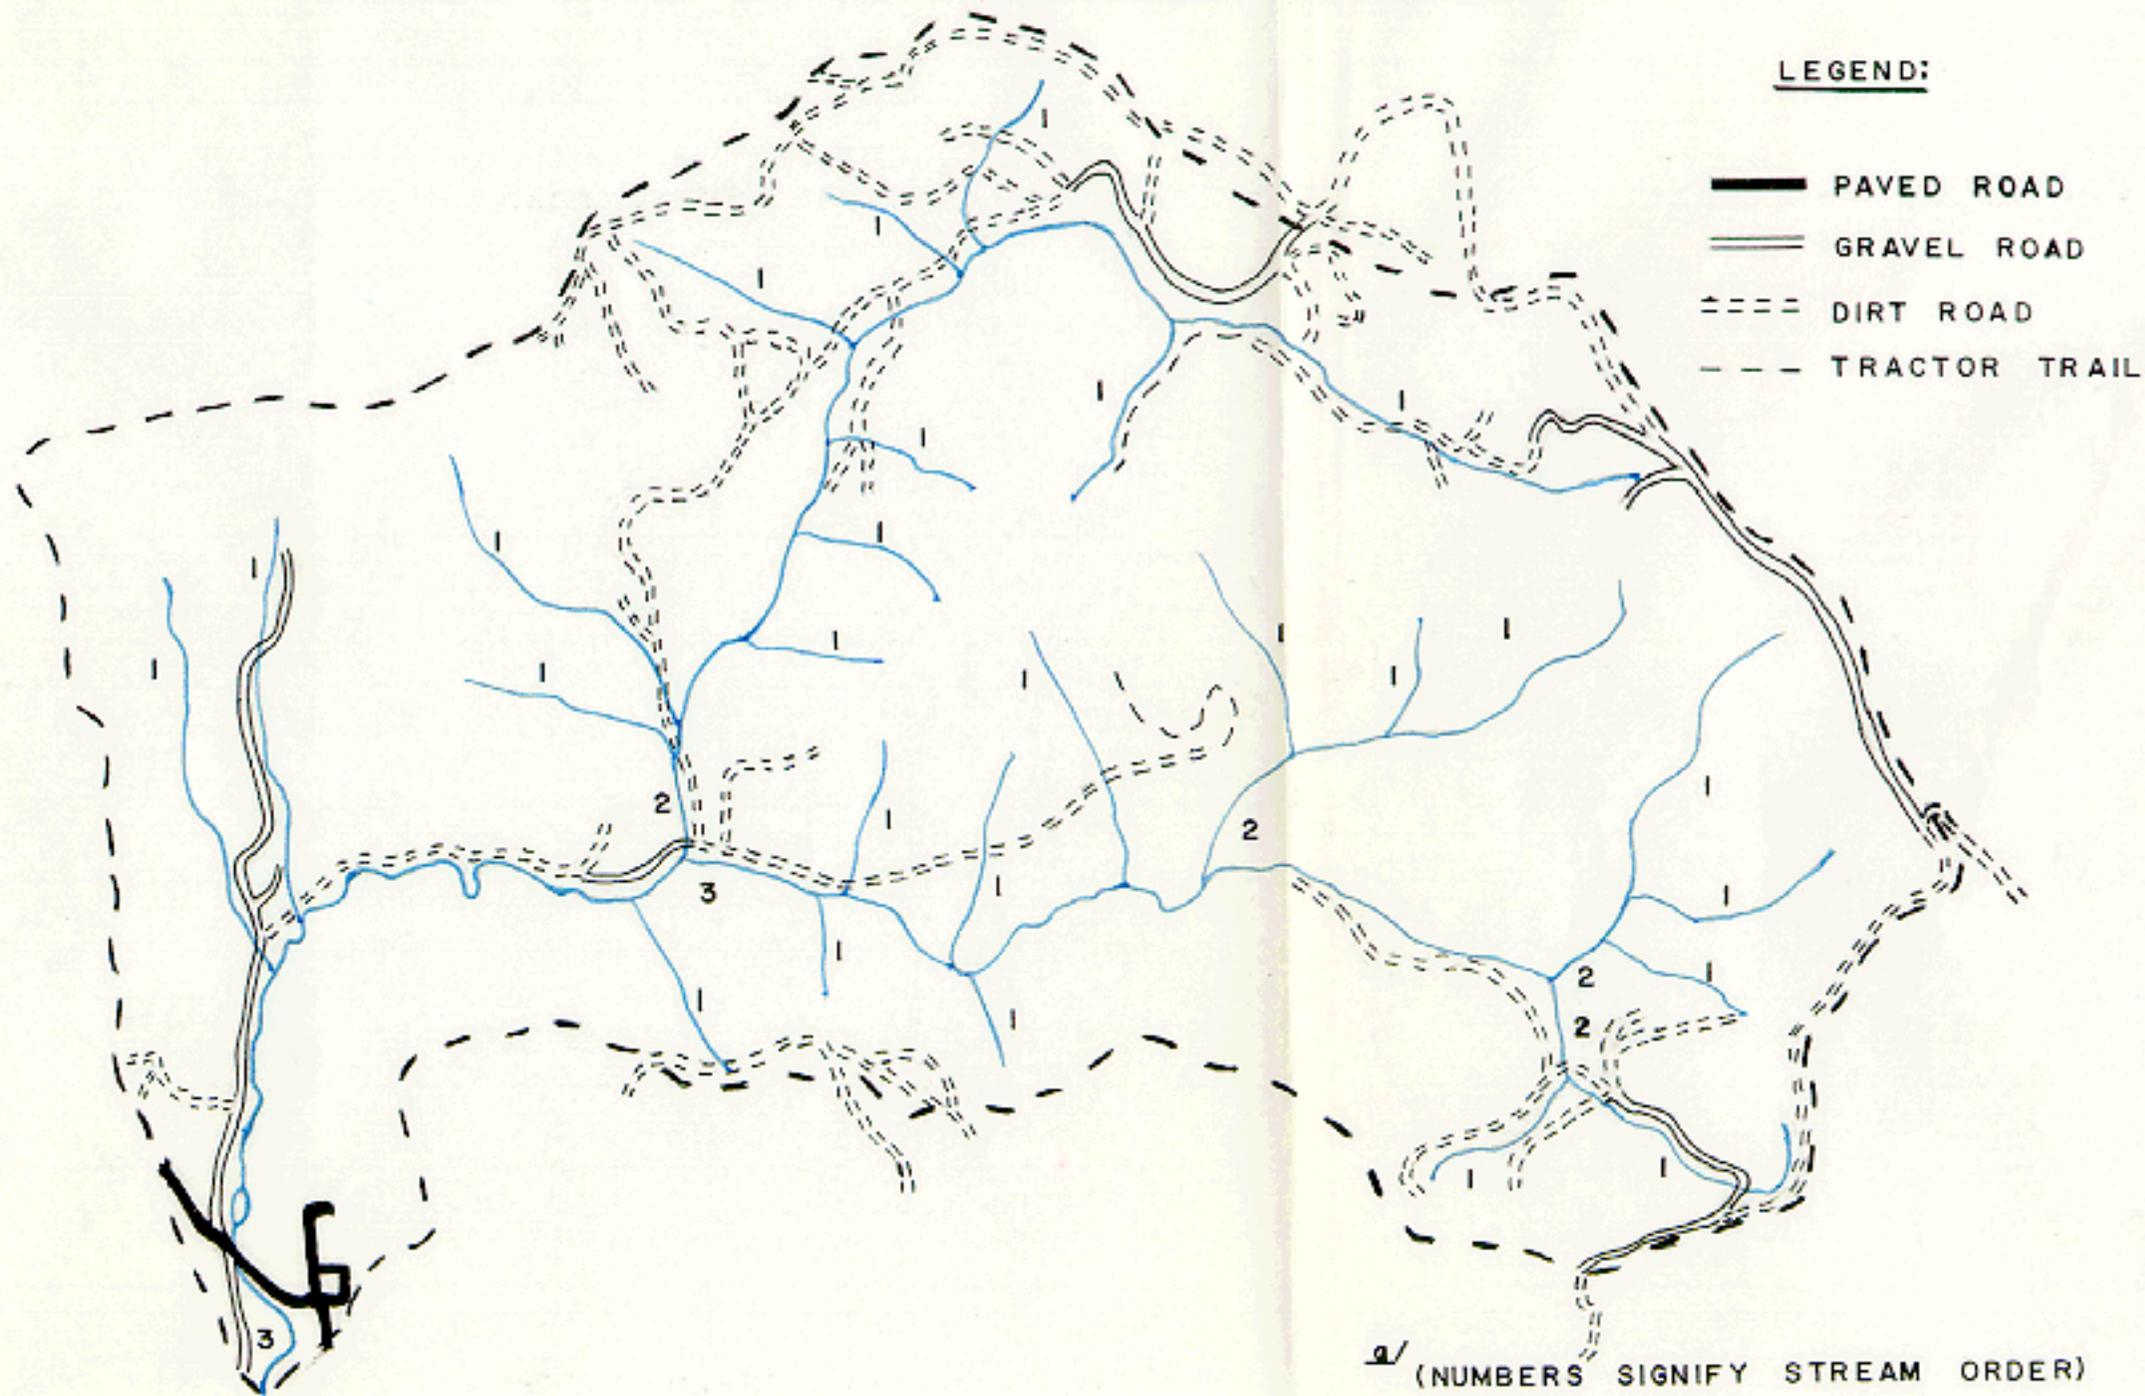

To provide a more intensive and **effective** analysis of the study area, the North Fork **Mattole** River Watershed has been subdivided into two basins, the North Fork Basin, and the **East** Branch North Fork Basin (Fig. 2).

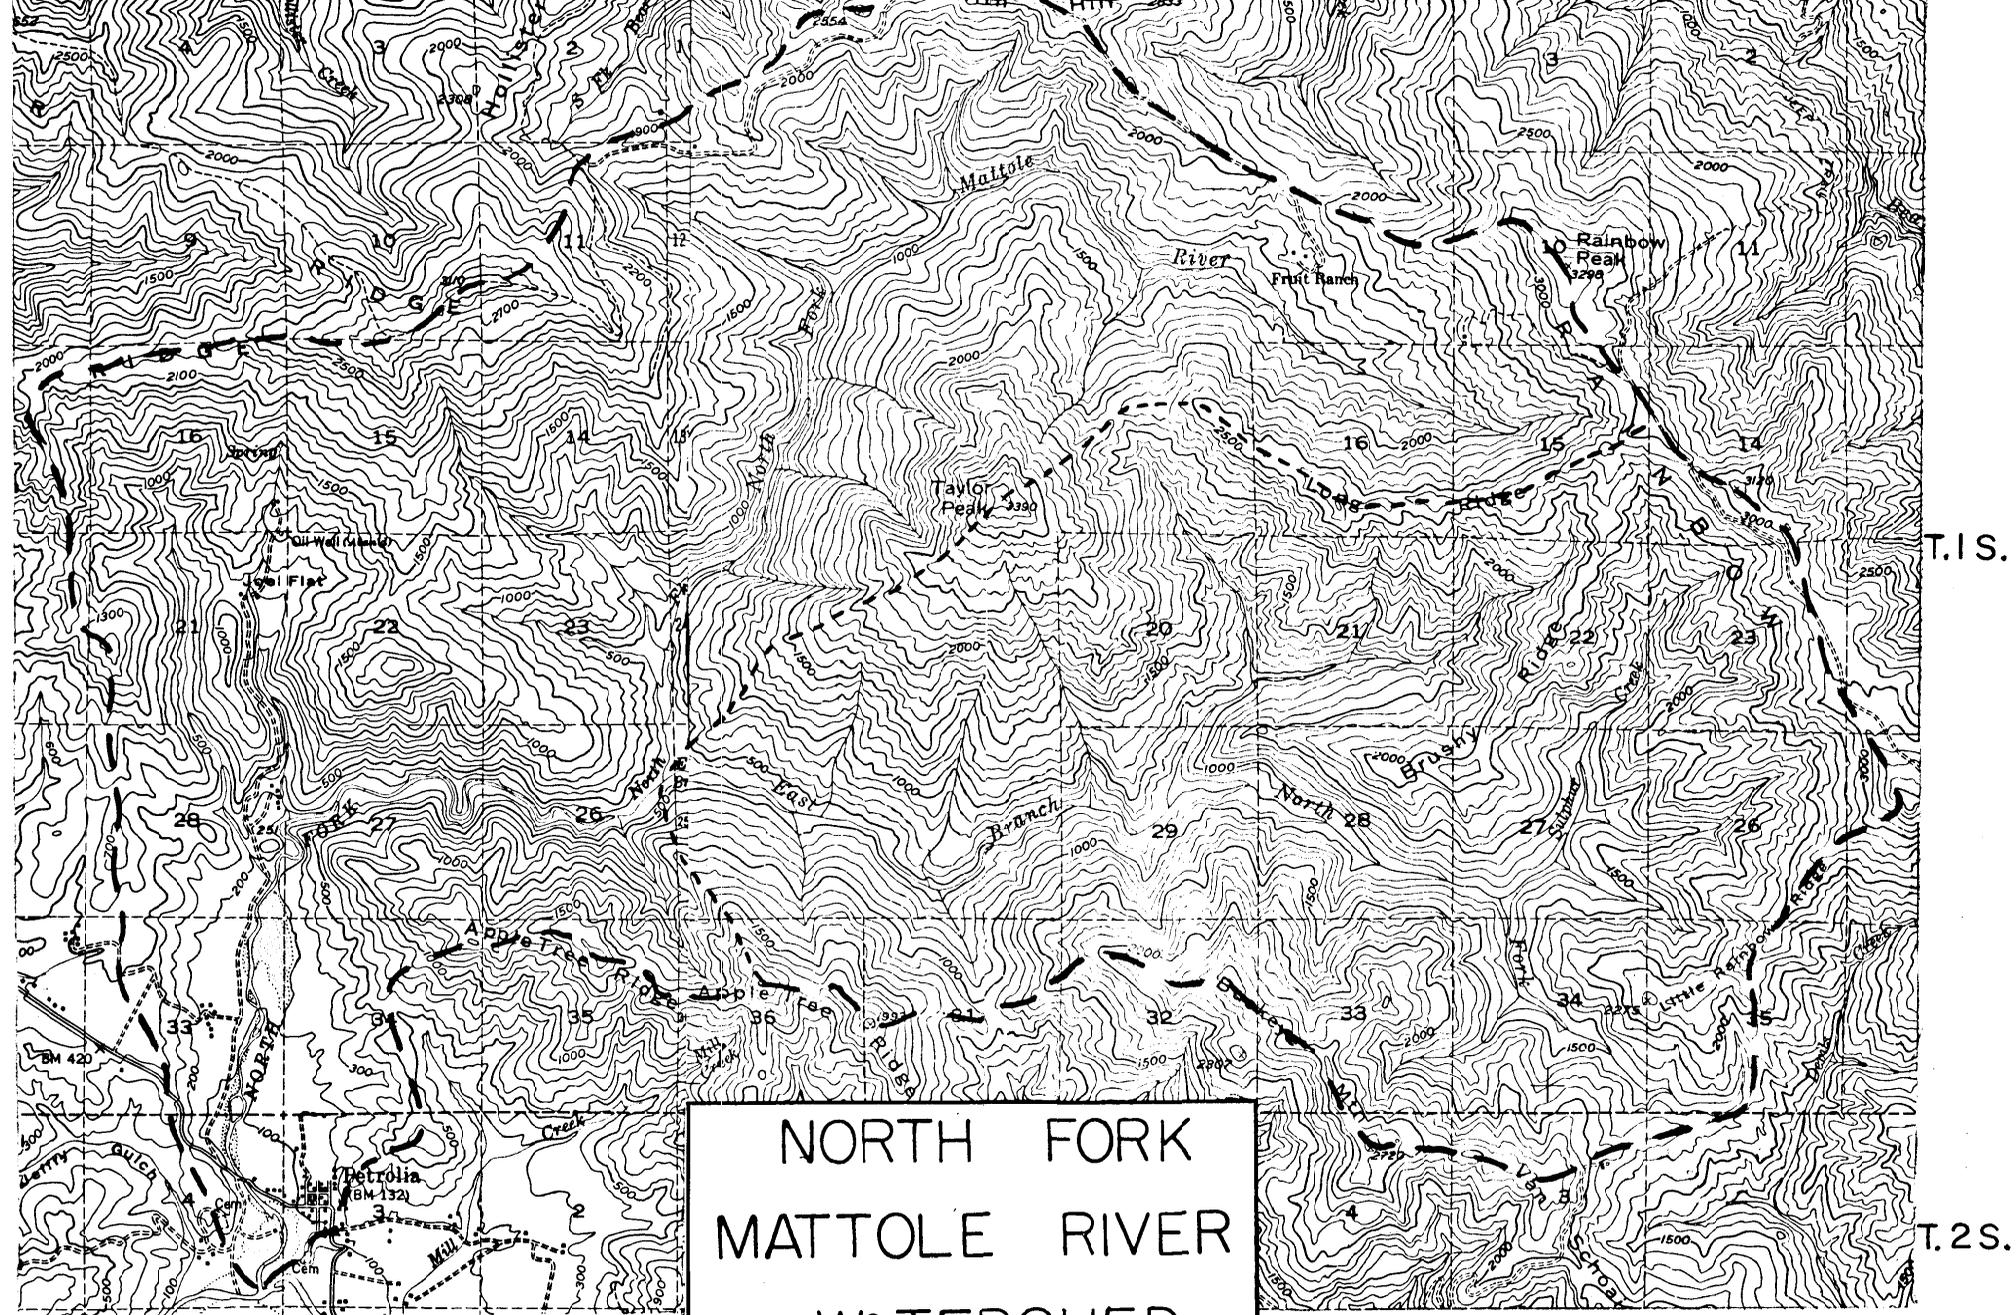

#### Location And Description

The **24,064** acre North Fork **Mattole** River Watershed is located in the rugged and sparsely-populated coastal mountains of southern Humboldt County, five miles inland from the Pacific Ocean (Fig. 1). Road access to the watershed is provided throughout the year from three **directions**: south from **Ferndale**, west from **Weott**, and northwest from **Garberville**. All three roads are maintained County Roads, branching off from U.S. Highway 101. The town of **Petrolia** is situated near the lower entrance of the watershed, where the North Fork empties into the main **Mattole River**. Access within the watershed itself is facilitated by 2.1 miles of paved road, **11.6** miles of gravel road, and **33.0 miles** of dirt road (Fig. 2A).

Three **major** tributaries comprise the stream network in the North Fork **Mattole River** Watershed. They are the following: **North Fork Mattole River**, **East Branch** of the North Fork, and **Sulphur** Creek, located near the headwaters of the **East** Branch (Fig. 2). Total length of perennial streams within the **watershed** is **46.7 miles**. According to the U.S. Geological Survey stream classification, no intermittent streams exist

in the watershed (Fig. 2). Additional stream length information can be found on page A, Table 5.

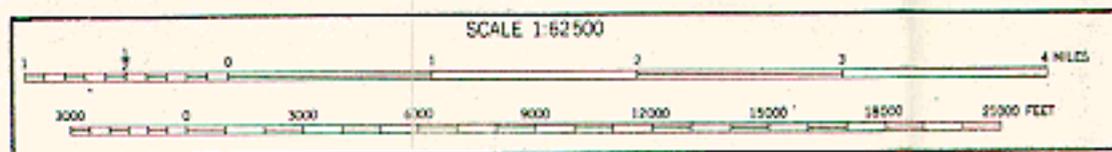

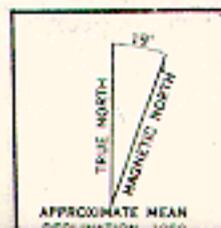

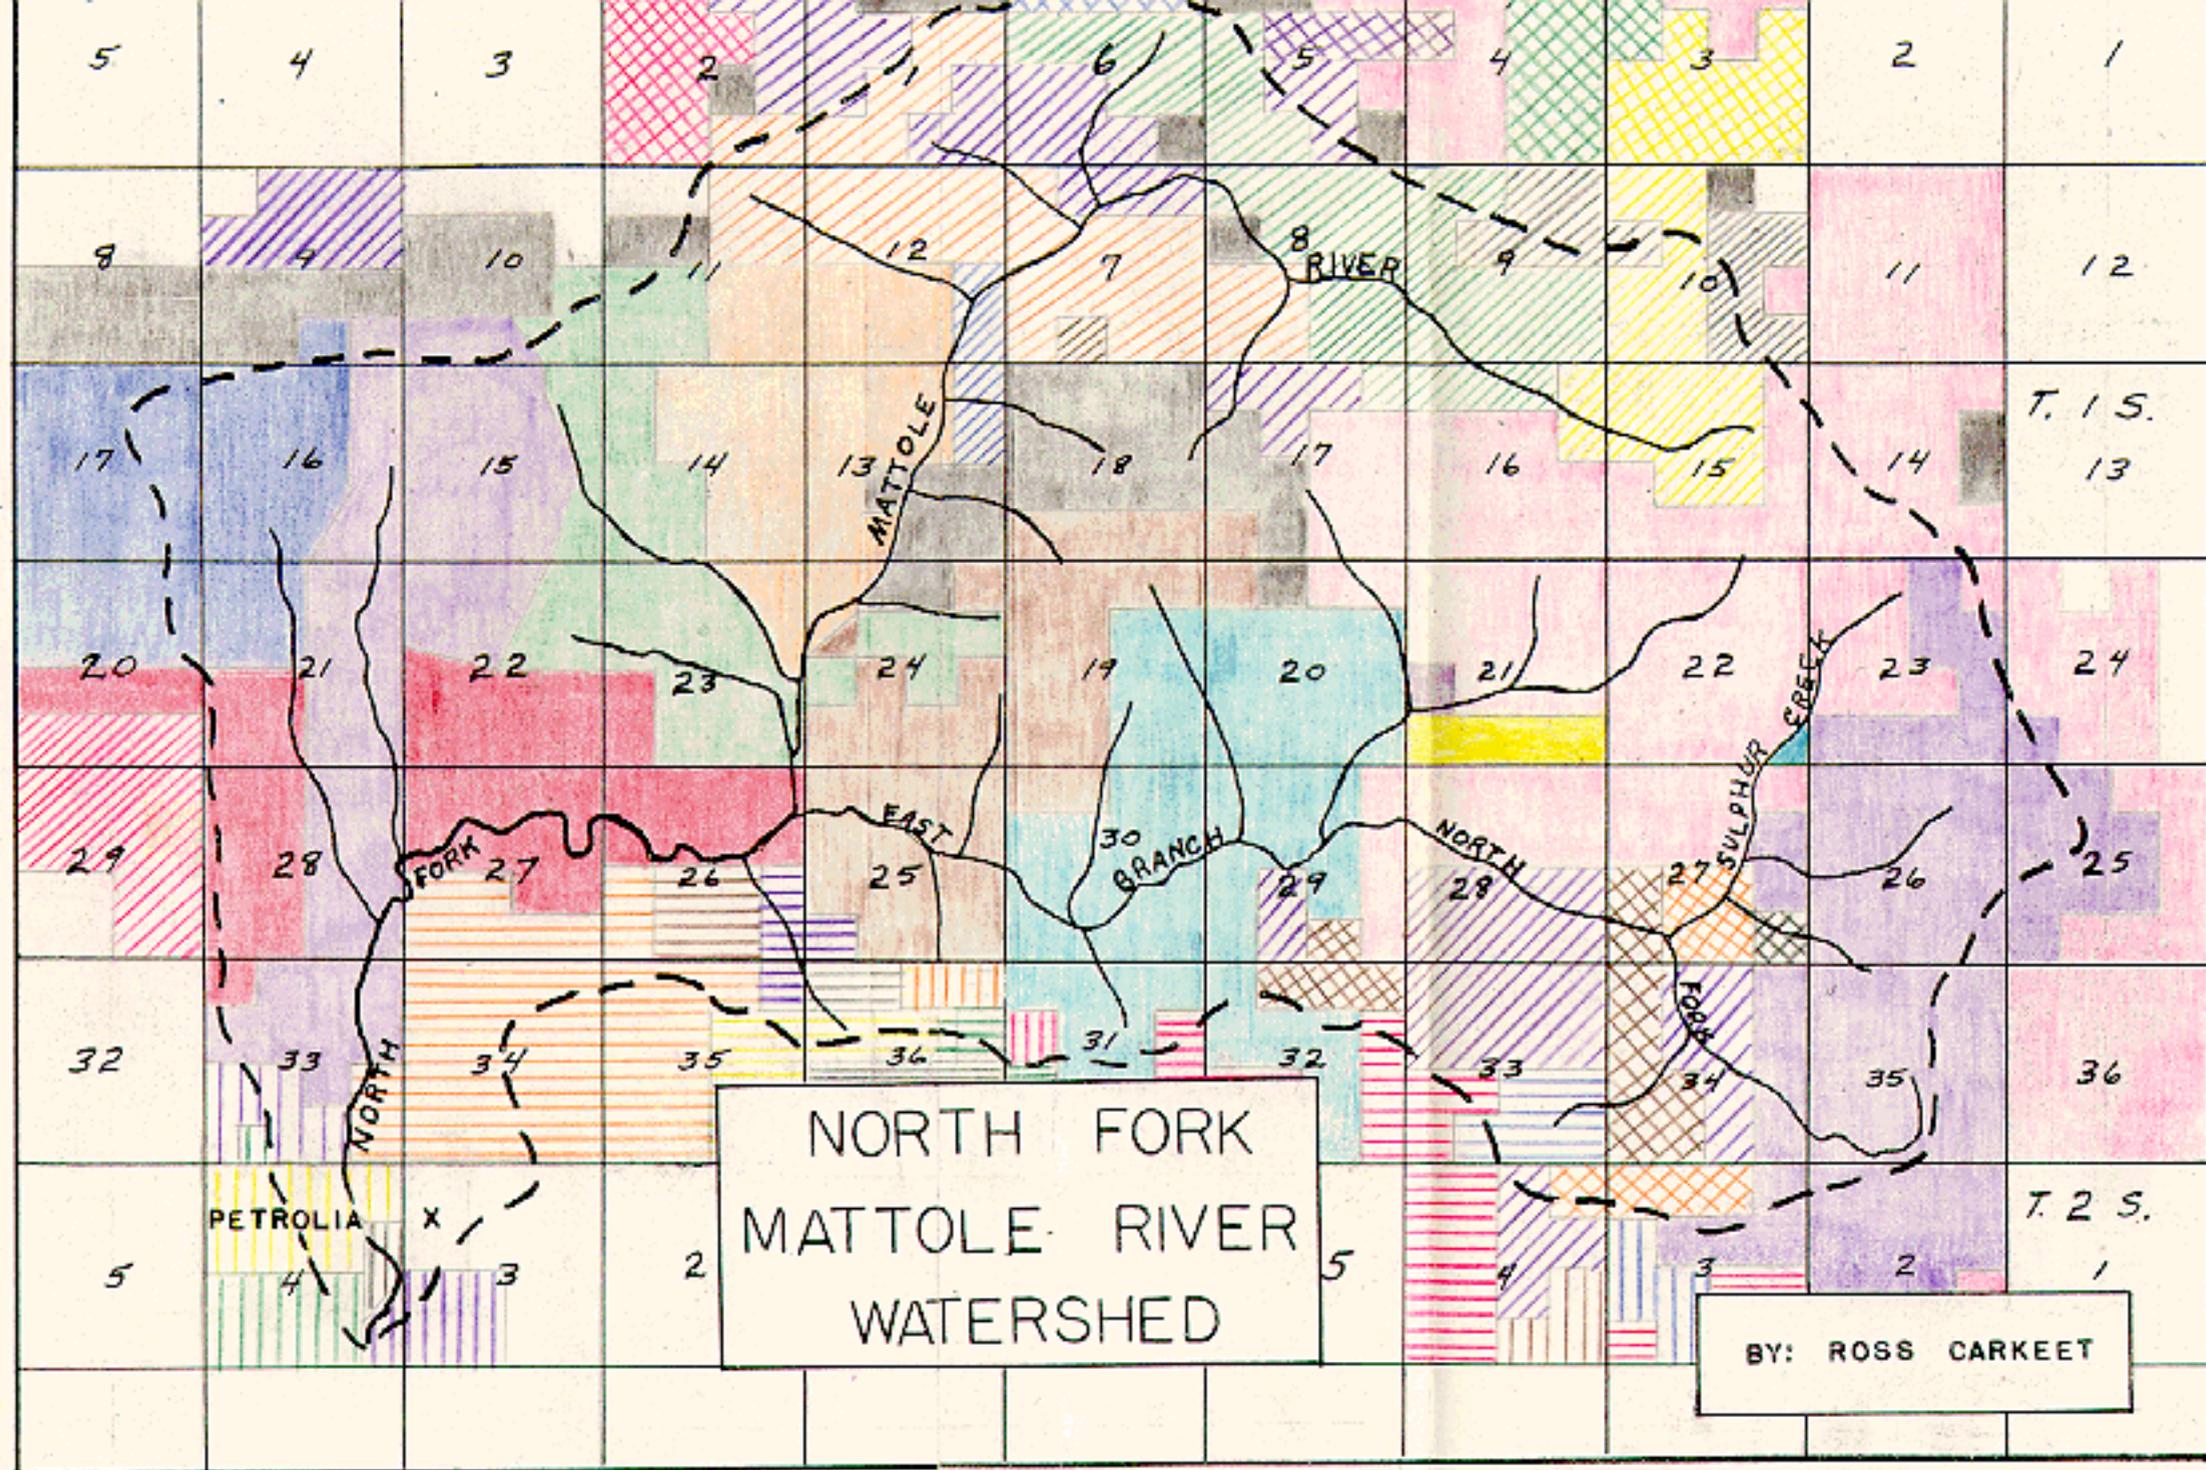

### Ownership

Figure 3 illustrates the present existing ownership pattern within the study area. All of the land within the watershed is in private ownership **except** for 40 acres of **unappropriated** land. The map displays the obvious; this being that numerous titles of **ownership** exist within the basin. However, large consolidated **parcels** are held by The Pacific Lumber Company and by J.L. and G. Chambers. The diversity of ownership pattern that exists within the watershed contributes significantly to the complexity of the management and use of the resources of the area. Diversity of ownership implies diversity of management objectives and specific land uses. It is more likely that widespread misuse and abuse of the land resources will occur in areas where ownership is not monopolistic, as will be **explained** later. **Addresses** of land owners **within** the watershed are given in **Table A, appendix.**

## CLIMATE

### Temperature

Published temperature data is **lacking** for the study area as well as for the immediate **Mattole Valley** area. An analysis of temperature data from other inland stations such as Alderpoint, or Scotia, for **which** published temperature information exists, might give reliable approximations of mean monthly maximum and minimum temperatures of the **study** area. In general, the temperature characteristics of the study area are **similar** in nature

to the coastal area of Humboldt County, where extremes between mean monthly maximum and minimum temperatures are uncommon. However, summer temperatures in the Mattole area are generally higher than along the coast, because summer fog usually disappears from the area by mid-morning. Midsummer maximum temperatures are often in the 90's (Community of Petrolia, 1962).

### Precipitation

A rain gage has been located in Petrolia by the Department of Water Resources. Records began in 1958, but have only been published for the period from 1963-1965. Table 1 and Figure 4 display the precipitation data for the published period. Two-thirds of the mean seasonal precipitation of 62.2 inches at Petrolia occurred during this period in the four months of November, December, January, and April. June through September are characteristically dry months, during which fire hazard becomes more acute throughout the area.

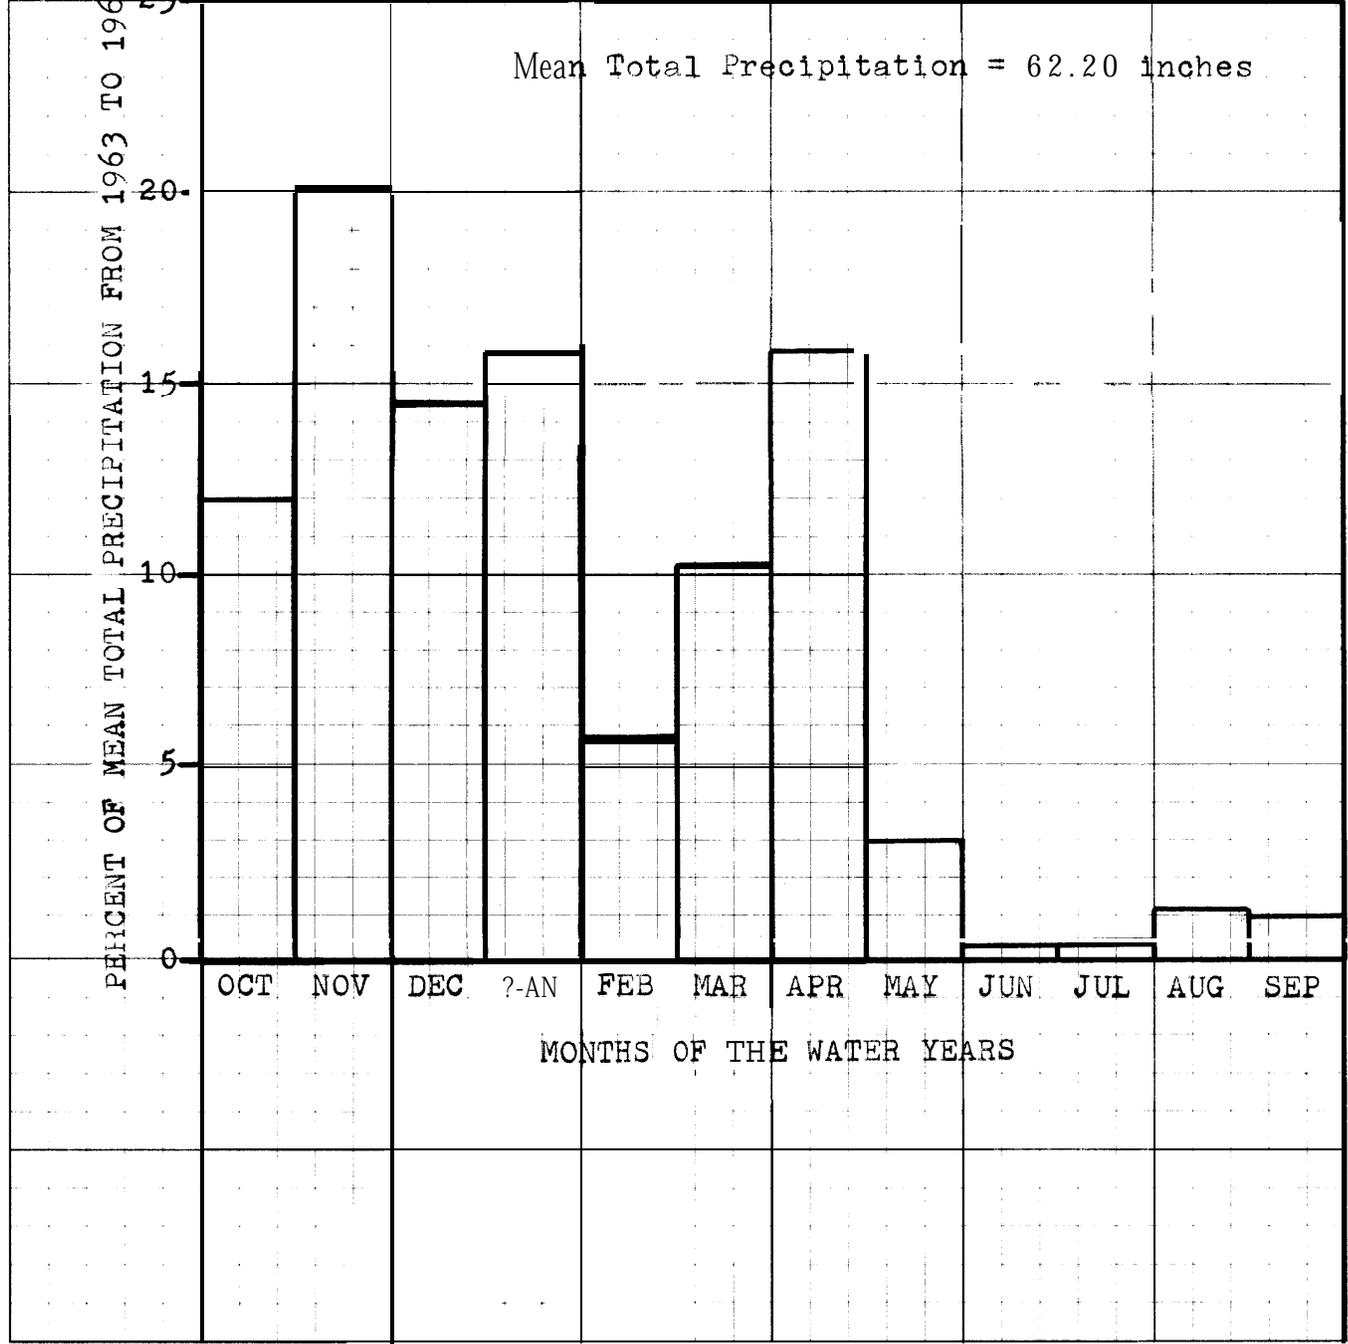

Figure 5 provides additional information on the mean annual precipitation of the watershed as a whole. Elevation increases eastward throughout the watershed, and as a result mean annual precipitation increases eastward to a maximum of 80 inches in the vicinity of the ridge south of Rainbow Peak (Rainbow Ridge). The general direction of storm movement in this area is from the southwest; thus precipitation increases in a northeasterly direction as the isohyets of Figure 5 suggest. Mean annual precipitation for the basin is 73.0 inches (U.S. Dept. of the Interior, 1960).

(BASED ON RECORDS FOR THE 50 YEAR PERIOD)

### Snowfall

Snowfall data is sorely lacking for this area, as well as for the remainder of Humboldt County. However, during the month of March in 1967, up to 22 inches of snow depth was reported above the 3,000 foot level in the vicinity of Rainbow Ridge within the watershed (Humboldt Standard, 1.967). This heavy snowfall presented a livestock feeding problem to cattlemen owning ranches in the vicinity. Ranchers in the area have agreed that this was the worst March that they have seen in the last 20 years as far as snow is concerned. Thus it can be expected that occasional, seasonal snow coverage in the upper elevations of the watershed can be expected.

### GEOLOGY

#### General Geology

Geologically speaking, in general the North Fork Mattole River Watershed is in a youthful stage. Numerous v-shaped canyons, rugged topography, and relatively straight stream channels are characteristics of this area and are representative of geologic youth. However, in the lower region of the watershed near Petrolia, the widening flood plain and the extensive alluvial deposition indicates that the geologic age is approaching maturity In this local area. Alluvial deposition has created a region of fertility in the lower portion of the watershed.

Structural geologic characteristics of the study area are depicted in Figure 6. The stratigraphy of the area is

Figure 6

could not be included  
due to its size.

It was a foldout geologic map.

essentially that of marine sedimentary rocks (graywacke and shale) of the Cretaceous geologic period.

### Specific Geology

The contact between the younger Tertiary sedimentary rocks and the older Cretaceous sedimentary rocks exerts a structural control that has resulted in the North Fork being diverted eastward, at a point two miles north of Petrolia. A few incised stream meanders exist along the North Fork in sections 26-28, T. 1S., R. 2W. Incised meanders are formed when geologically older stream areas with meandering tributaries undergo regional uplift, thus causing the stream to rapidly downcut where mature meanders once existed.

Figure 6 also shows that a northwest-trending fault shear zone (The Mattole Fault Shear Zone) crosses the watershed near the location where the North Fork and the East Branch of the North Fork divide. A closer examination of the shear zone is offered in Figure 7. Township, Range, and Section designations of this geologic map allow the shear zone to be pinpointed on the topographic map (Fig. 2). The significance of the shear zone is twofold: 1) A one-time productive area of oil accumulation exists near the shear zone, and 2) the shear zone is responsible for initiating local landslides where unstable soils exist.

## SOILS AND VEGETATION

### Forest Soils And Associated Vegetation

Use of the Soil-Vegetation Map (Figure 8) and accompanying Tables 2 and 3 provide vital information on vegetation-soil

TABLE 3 - ADDITIONAL INFORMATION FOR USE WITH THE  
NORTE FORK MATTOLE RIVER WATERSHED SOIL-VEGETATION MAP<sup>a/</sup>

SOILS

Soils are designated on the map by symbols written as fractions. The numerator of the fraction designates the soil series. Depthclass of soil is designated by the first digit in the denominator of the fraction:

| <u>Depth Class</u> | <u>Symbol</u> | <u>Depth in Feet</u> | <u>Depth Class Name</u> |
|--------------------|---------------|----------------------|-------------------------|
|                    | 1             | less than 1          | Very Shallow            |
|                    | 2             | from 1 to 2          | Shallow                 |
|                    | 3             | from 2 to 3          | Moderately Shallow      |
|                    | 4             | from 3 to 4          | Moderately Deep         |
|                    | 5             | more than 4          | <b>Deep</b>             |

A second number in the denominator of the fraction (separated from the depth or other phase symbol by a hyphen) indicates the dominant slope class in the delineated area:

- Slope class 1 is less than 30%
- Slope class 2 is from 30 to 50%
- Slope class 3 is from 50 to 70%
- Slope class 4 is more than 70%

Letters immediately following the depth class symbol in the denominator are used to designate other phases as follows:

- S = Coarse fragments in the soil (gravel, cobbles, or stones)
- E = Severe erosion

TIMBER SITES

Douglas-fir types are graded in terms of the total height that average dominant and codominant Douglas-fir trees reach at 100 years of age--by 30-foot classes. These classes are designated by Roman numbers on the map as follows:

| <u>Site Class</u> | <u>Symbol</u> | <u>Height in feet of dominant and codominant trees at 100 years</u> |
|-------------------|---------------|---|
|                   | I             | 200   |
|                   | II            | 170   |
|                   | III           | 140   |
|                   | IV            | 110   |
|                   | V             | 80  |

<sup>a/</sup> From Black (1964)

VEGETATION

Vegetation symbols are listed on the map in decreasing order of ground coverage density. The following symbols represent the vegetation within the North Fork Mattole River Watershed on the Soil-Vegetation map:

| <u>Mapbol</u> | <u>Common Name</u> | <u>Scientific Name</u>          |
|---------------|--------------------|---------------------------------|
| BP            | Chaparral Broom    | <u>Baccharis pilularis</u>      |
| C             | Canyon Live Oak    | <u>Quercus chrysolepis</u>      |
| Cso           | Jim Brush          | <u>Ceanothus sorediatus</u>     |
| Ct            | Blue Blossom       | <u>Ceanothus thyrsiflorus</u>   |
| D             | Douglas-fir        | <u>Pseudotsuga menziesii</u>    |
| G             | Grand Fir          | <u>Abies grandis</u>            |
| H             | California Buckeye | <u>Aesculus californica</u>     |
| L'            | California Laurel  | <u>Umbellularia californica</u> |
| M             | Madrone            | <u>Arbutus menziesii</u>        |
| M             | Bigleaf Maple      | <u>Acer macrophyllum</u>        |
| Pta           | Western Bracken    | <u>Pteridium aquilinum</u>      |
| T             | Tanoak             | <u>Lithocarpus densiflora</u>   |

Other Symbols:

Description

|                 |   |
|-----------------|---|
| <u>Gr</u> ..... | Grasses and other associated herbaceous plants--includes meadows  |
| <u>Ba</u> ..... | Bare or litter--covered ground., essentially devoid of vegetation |

Figure 8

SOIL-VEGETATION MAP

could not be included  
due to its size.

relationships in the watershed.

The **Hugo soil series covers** approximately two-thirds of the total watershed area. This fact is supported by the coloration on the Soil-Vegetation Map. The Hugo soil series possesses moderate suitability for **timber** production and drains well in most cases. However, surface **erodability** of **this** soil is high if sites are severely **disturbed** (Black, 1964). Mean depth of the soil throughout the watershed is four feet. The prevalent vegetative covering on areas where Hugo soil exists is Tanoak (Lithocarpus densiflora), Madrone (Arbutus menziesii), California Laurel (Umbellularia californica), and Douglas-fir (Pseudotsuga menziesii), in varied **arrangements** of ground coverage density. Douglas-fir is usually classified as a minor **component** of the vegetation throughout the watershed in terms of density (Fig. 8).

Other forest soils in the watershed **occupying** relatively small areas are: Melbourne (814), Usal (818), Hoover (822), Boomer (7118), and Atwell (823). The significance of the Atwell soil series in certain locations should not be overlooked. This soil series is notorious for instability following site disturbance. Instability problems with this soil have arisen in various locations throughout Humboldt County (Boe, 1963).

#### Grassland Soils And Associated Vegetation

Typical grassland soils of the watershed are Kneeland (835), and McMahon (839). A large percentage of the grassland area in the watershed is found on the transition-classified Wilder (840) soil series, as well as the wood-grassland

classified Zanone (852) soil series. The absence of other woodland vegetation with the prevalence of grasses on the last two mentioned soil series in the watershed, has resulted in the classification of these two soils as representing typical grassland soils for the study area.

#### CLASSIFICATION

Table 4 and Figure 9 provide information on land classification within the North Fork Mattole River Watershed. Approximately one-fourth of the total watershed area supports commercial forest land with stands of Douglas-fir ranging in density from 10 to 70 percent. Only 2.2 percent of the total watershed area supports stands of Douglas-fir in densities ranging from 71 to 100 percent. Of significant importance is the fact that nearly 25 percent of the total watershed area has been logged of 70 percent of the merchantable timber volume within the last five years; whereas only 3.2 percent of the total watershed area has been logged prior to five years, to the extent that no merchantable timber remains to date.

A comparison between the 1957 Soil-Vegetation Map (Fig. 8), and the 1962 Timberstand Maps in the Humboldt County Assessor's Office (upon which Fig. 9 is partially based) indicate a change during the five year period in the amount of area classified as grassland. Total area of grassland on the Soil-Vegetation Map 4s computed as 7,500, or 31.2 percent of the total watershed area. Total area of grassland in Figure 9 is 8,220 acres, or 34.1 percent of the total watershed area. During this five year period, 720 acres of the watershed has been converted from

a/ Douglas-fir

some other vegetative cover (or bare ground) to grassland.

Approximately 1,000 acres of irrigable farmlands are located in the lower portion of the watershed, immediately north of **Petrolia**. Brush and hardwoods are found in minor quantities throughout the watershed.

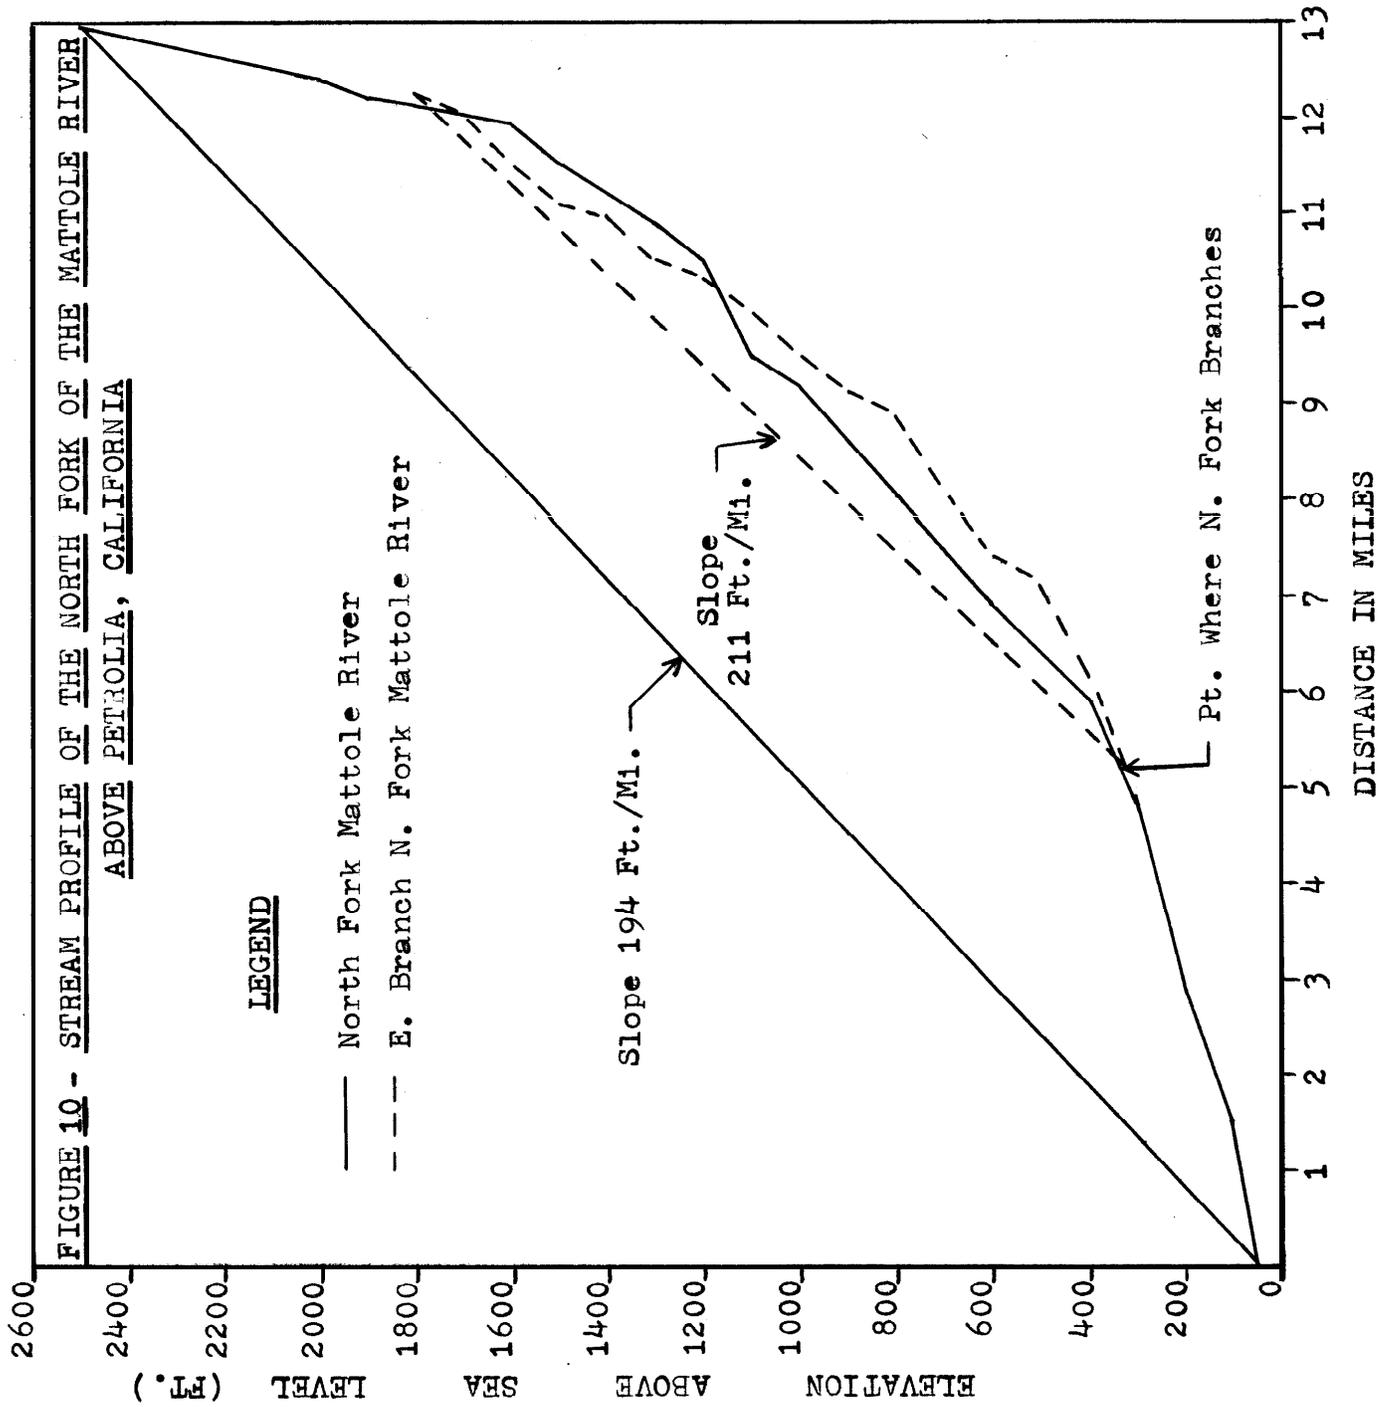

### HYDROLOGIC CHARACTERISTICS OF THE WATERSHED

#### Drainage

The drainage pattern of the tributaries within the study area is basically dendritic, although a characteristic radial drainage pattern exists in the vicinity of Taylor Peak, in the center of the watershed. A **dendritic** drainage pattern indicates **that** no variation exists in the resistivity of the rocks to influence the stream pattern. In other words, the pattern suggests homogeneity of geologic formations with a definite lack of structural control, such as **faulting**, **jointing**, **folding**, etc. A radial drainage pattern exists on Taylor Peak because the North Fork and East Branch of the North Fork of the **Mattole have downcut** in different directions, and the tributaries have circled to **almost** join again, thus leaving a higher residual **landform** (Taylor Peak) between them.

#### Stream Profile

The profile of the main stream of the North Fork and the East Branch of the North Fork have been plotted in Figure 10. The mainstream of the North Fork extends **to** a region of higher elevation than does the East Branch, the difference being 700 vertical feet. The fall of each main stream differs to a degree, and the values suggest that the East Branch of

the North Fork has a slight **advantage** in sediment transport potential and cutting power over the **main** stream of the North Fork basin. A larger fall in feet per mile **implies** that stream velocity will be greater, with a resulting increase in scouring potential.

#### Drainage And Stream Density

Page A, of Table 5 provides stream and drainage density **information** for the study area. It should be noted that both expressions of density are largest in the basin of the East Branch of the North Fork, although the comparative differences are not extreme.

#### Compactness Coefficient

The compactness coefficient is used to express the relationship of a hydrologic basin to that of a circular basin having the same area as the hydrologic basin. A **circular-** shaped basin is the most hazardous from a drainage standpoint because it will yield the shortest time of concentration before peak flow occurs in the basin. Compactness coefficient values **approaching** unity (i.e. 1.00) indicate drainage basins that are circular. The following formula is used to compute the coefficient: Compactness Coefficient =  $\frac{\text{Basin Perimeter In Miles}}{2\sqrt{\pi}(\text{Basin Area In Mi.}^2)}$ . Compactness coefficient values on page B, Table 5 indicate that the basin of the East Branch of the North Fork possesses the most hazardous natural flood potential; while the North Fork basin (because of its longitudinal shape) is significantly less critical as far as timing of peak flow is concerned.

TABLE 5 - PHYSIOGRAPHIC WATERSHED PARAMETERS OF THE NORTH FORK MATTOLE RIVER WATERSHED

| <u>Area</u>                     | <u>Acres</u>  | <u>Sq. Miles</u> |
|---------------------------------|---------------|------------------|
| North Fork Basin                | 13,765        | 21.5             |

### Stream Order

Stream Order is a classification reflecting the degree of branching, or bifurcation, within a basin. A stream order of 1 is assigned to small, unbranched tributaries, order 2 is given to those streams which have branches of the first order only, order 3 to streams with branches of second and lower orders, etc. (Linsley, Kohler, and Paulhus, 1949).

A map designating stream orders in the watershed is displayed in Figure 2A. The study area contains 30.2 miles of 1st order streams and 8.2 miles of 3rd order streams. The magnitude of the length of 3rd order streams indicates that the watershed is efficiently drained, in spite of its youthful topography and the presence of a less than well-integrated stream system.

### Stream Discharge

A stream-gage site exists within the study area approximately one-half mile west of Petrolia and seven-tenths of a mile upstream from the lowest end of the watershed. Discharge records are available for the watershed from June of 1951 to September, 1957. Table 6 lists separate monthly and yearly mean discharge values for the recorded period.

Values in Table 6 were used to construct Table 7, in which the "pooled" mean monthly and annual discharge values are given for the recorded period. The monthly values are expressed in Table 7 as a percentage of the mean total annual runoff for the watershed, which is computed to be 128,543 acre-feet.

**TABLE 6 - ADDITIONAL STREAM DISCHARGE INFORMATION a/**

**MATTOLE RIVER BASIN**

621

4655. North Fork Mattole River at Petrolia, Calif.

Location.--Lat 40°19'35", long 124°17'35", in NE 1/4 sec. 4, T.2 S., R.2 W., on left bank 0.5 mile west of Petrolia and 0.7 mile upstream from mouth.

Drainage area.--37.6 sq ml.

Records available.--June 1951 to September 1957.

Gage.--Water-stage recorder. Altitude of gage is 55 ft (from topographic map). Prior to Oct. 6, 1953, at site 200 ft downstream at same station.

Average discharge.--6 years (1951-57), 177 cfs (ii 3,160 acre-ft per year).

Extremes.--1951-57: Maximum discharge, 9,600 cfs Dec. 21, 1955 (gage height, 10.60 ft), from rating curve extended above 1,300 cfs by logarithmic plotting; minimum, 2.0 cfs Sept. 4, 1955.

Remarks.--Small diversions for irrigation above station.

Monthly and yearly mean discharge, in cubic feet per second

<sup>a/</sup> From U.S. Geological Survey (1964)

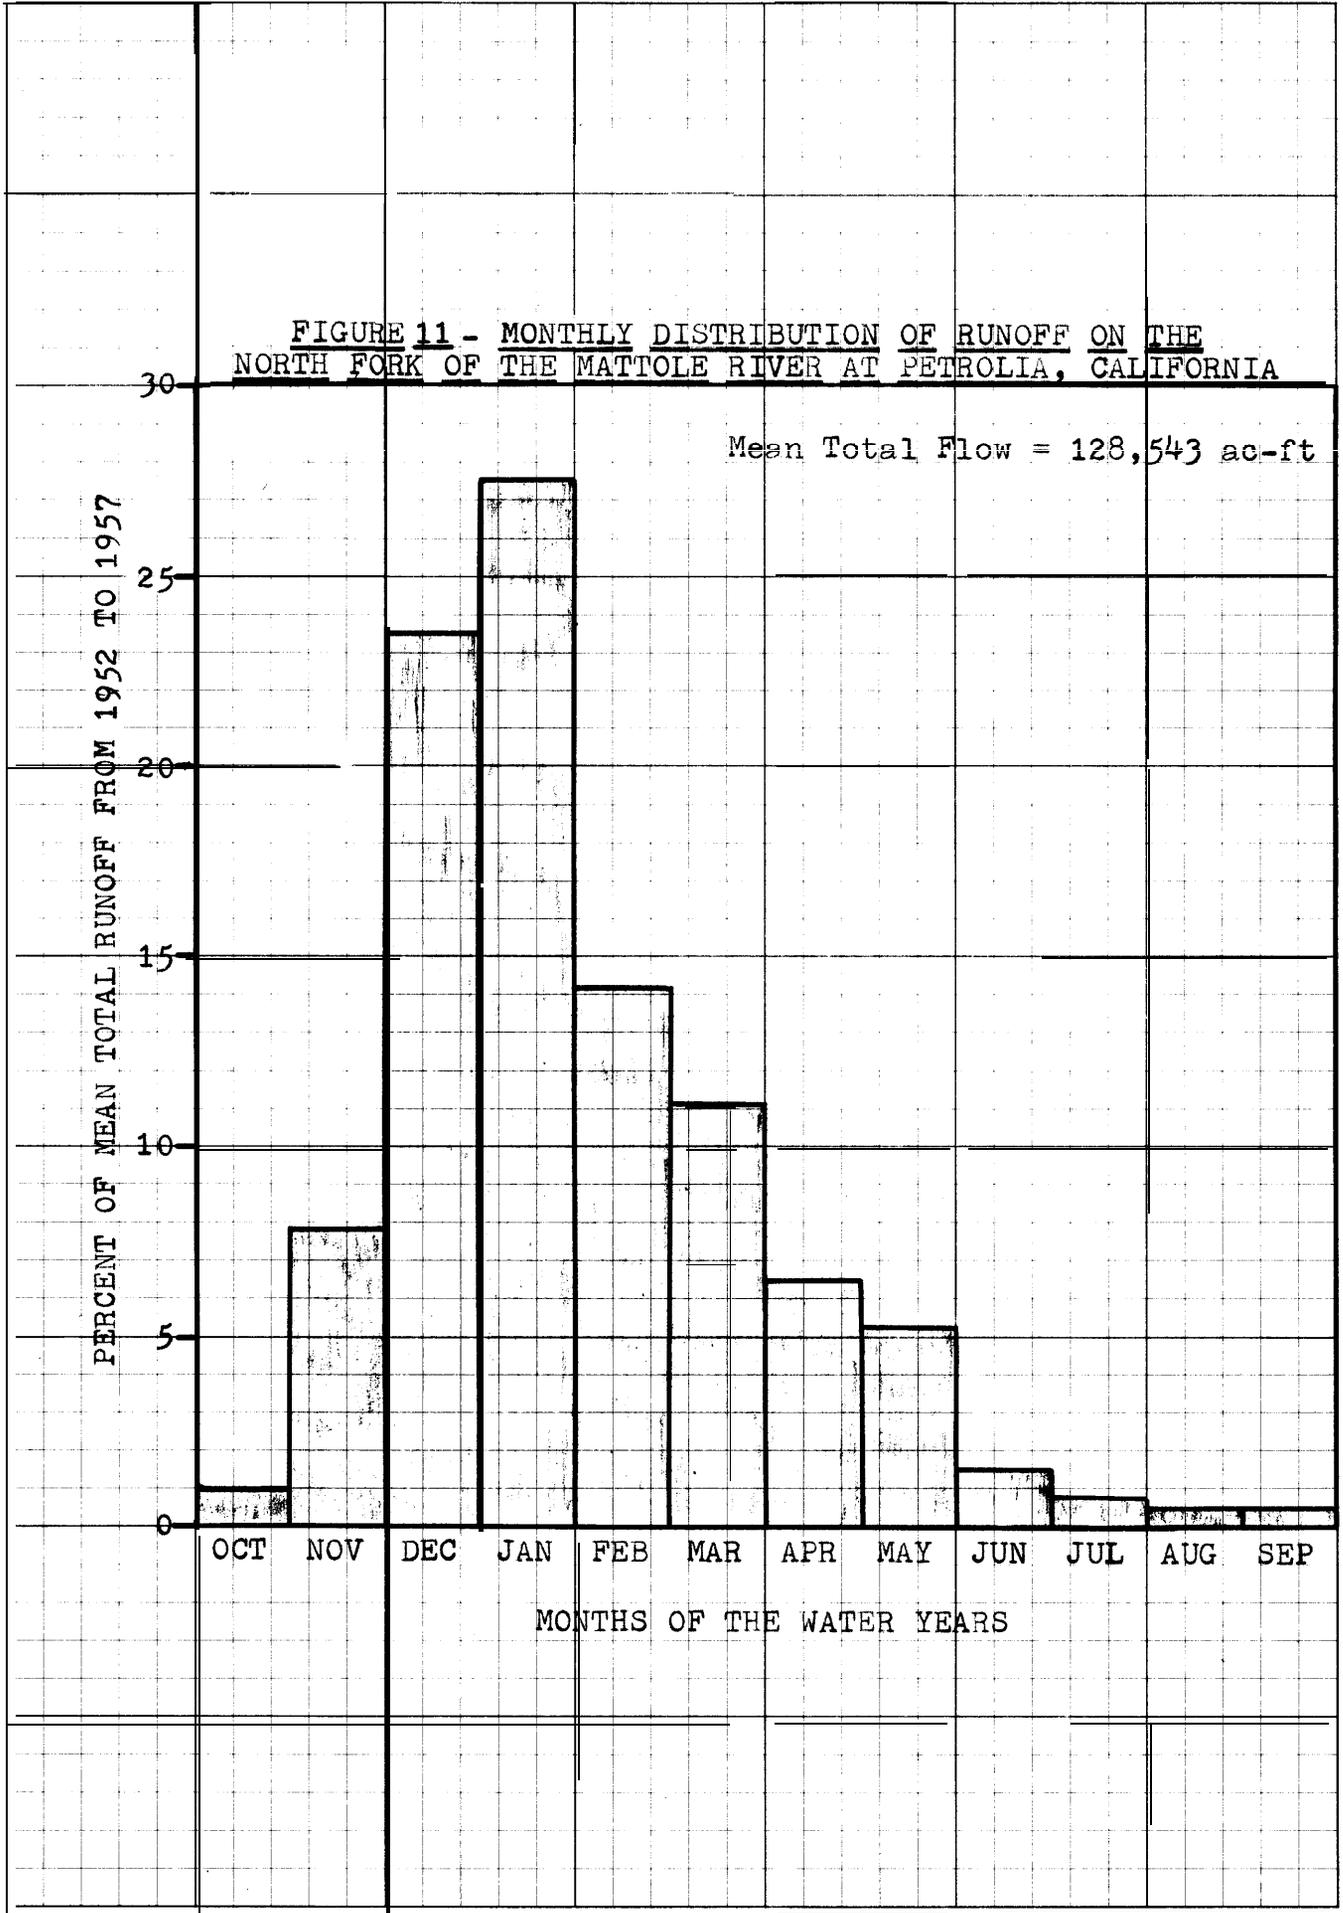

<sup>b/</sup> R.O. Refers to Runoff

The relationship of mean monthly discharge in Table 7 to the percent of mean total annual runoff is portrayed graphically in Figure 11. During the recorded period of discharge measurement, approximately 50 percent of the mean total runoff from the watershed occurred during the months of December and January. Extremely low flows occurred from June through September. A comparison between the Precipitation Graph (Fig. 4) and the Runoff Graph (Fig. 11) can be made even though they represent different periods of time. In general, precipitation and runoff are heaviest from November to January, and lowest from June to September. Heavy precipitation in March and April would probably not be reflected as a monthly increase in runoff rate, because the precipitation would be recharging a soil profile that is beginning to desiccate.

#### Flow Duration Curve

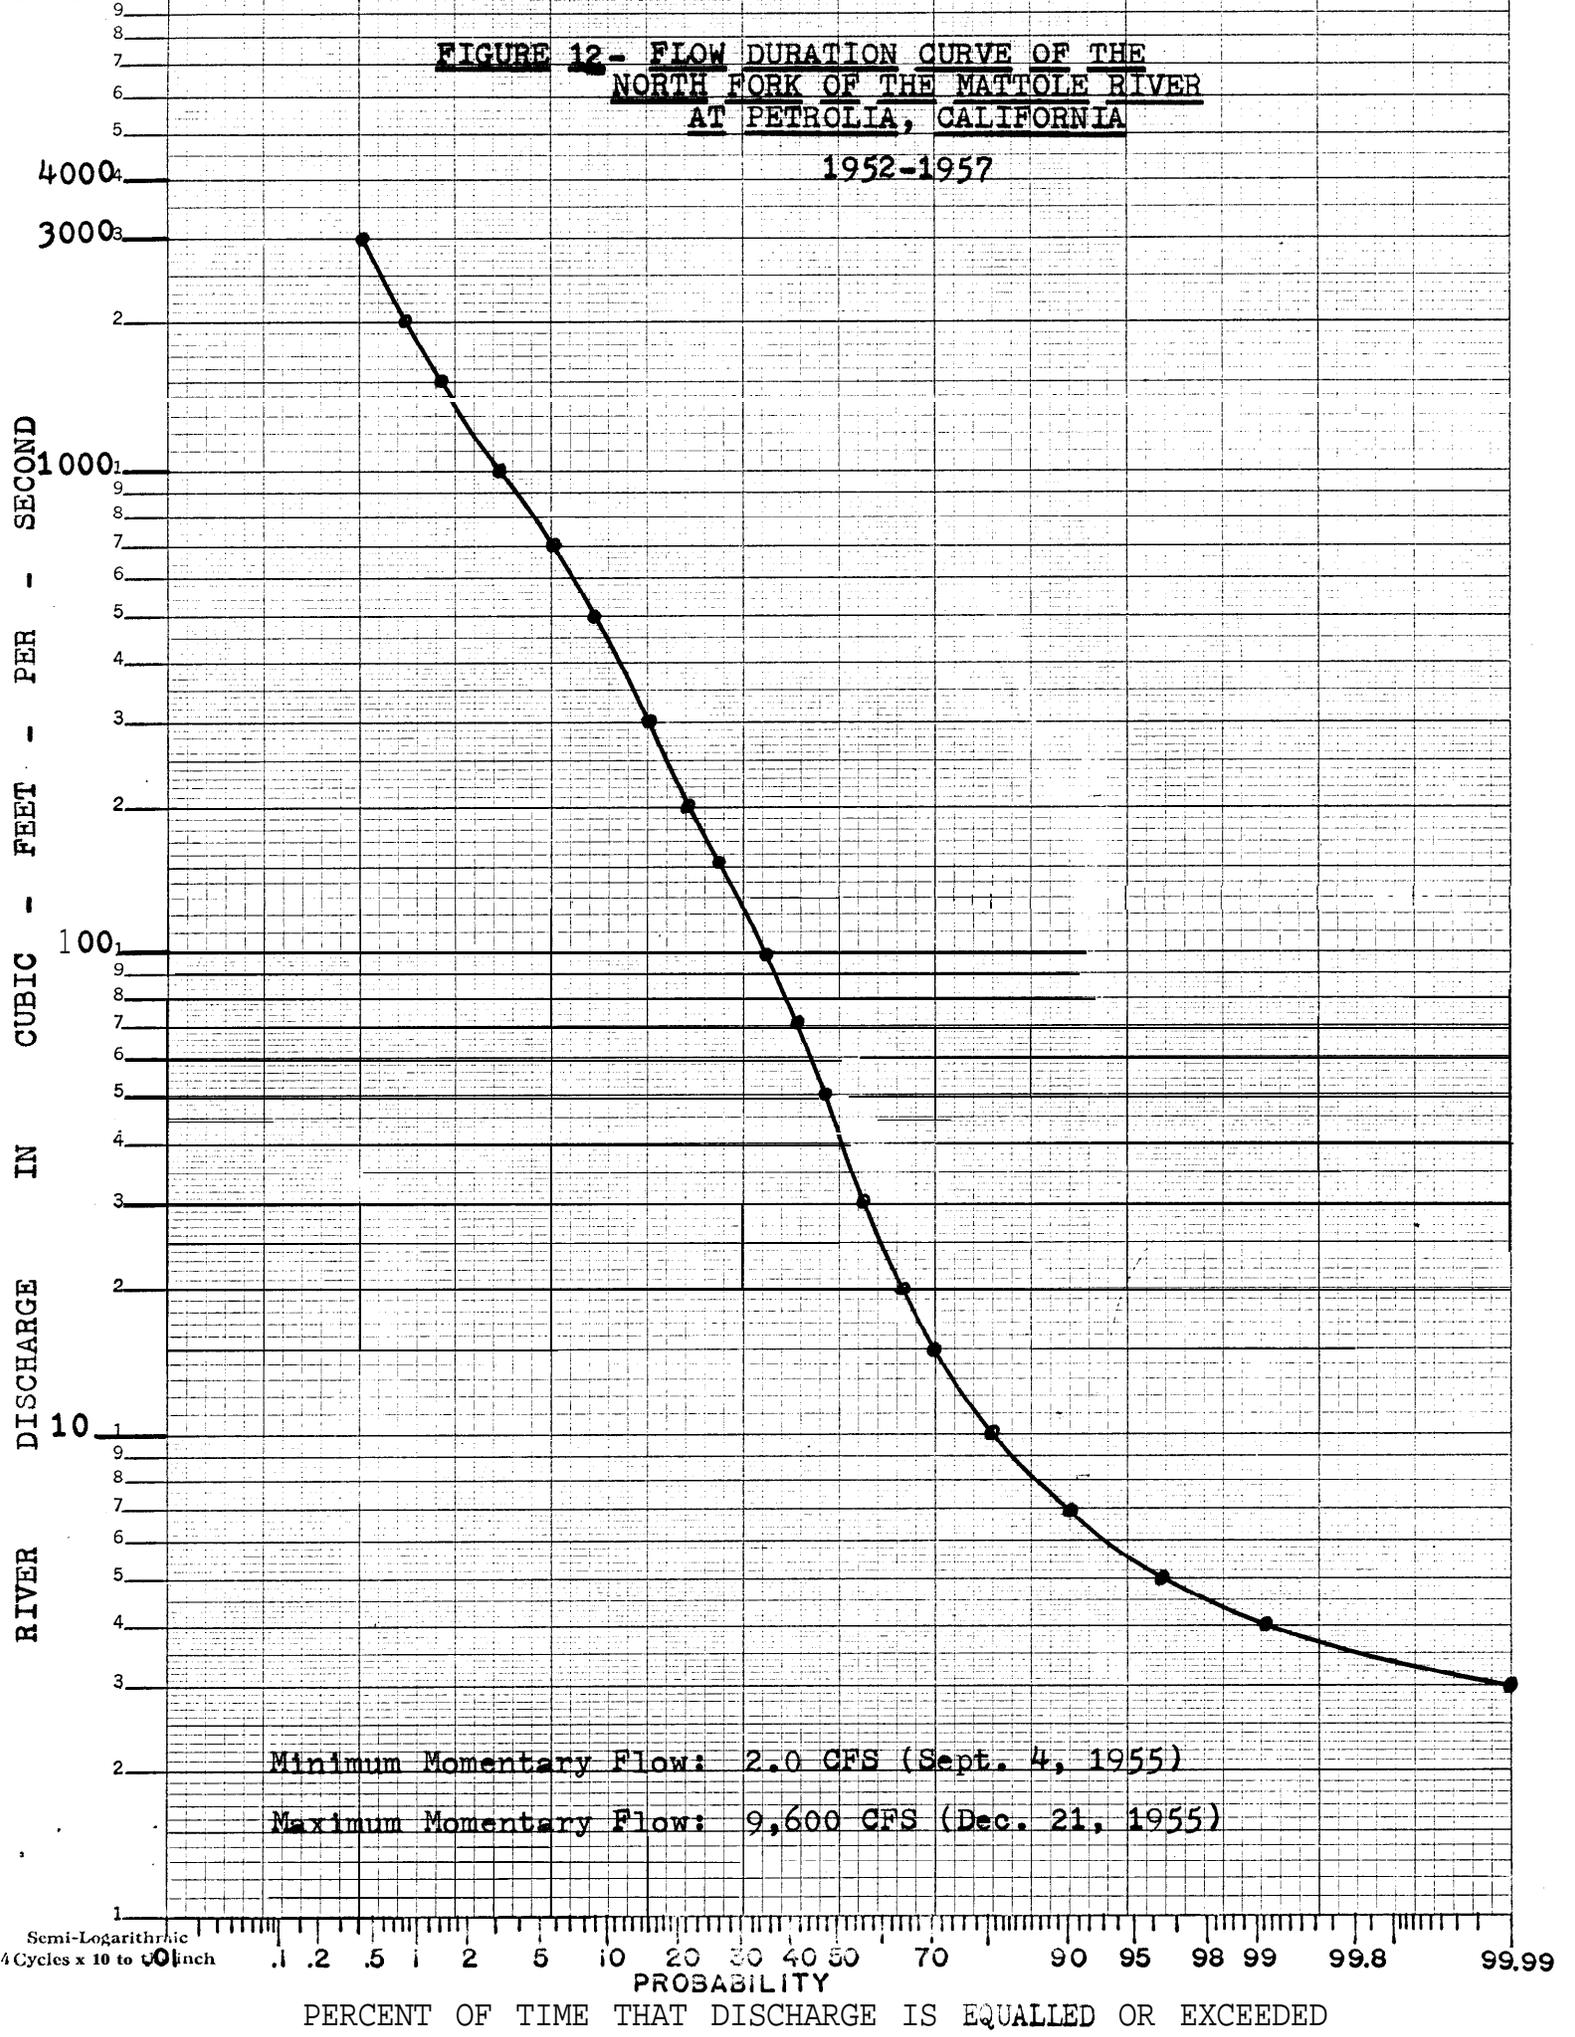

A flow-duration curve (Figure 12) has been constructed from annual discharge records compiled by the U.S. Geological Survey (U.S.G.S., 1952-1957). The table used (Table B) in compiling the necessary information to plot the curve is included in the appendix.

The curve provides a description of stream behavior. A relatively straight curve, such as that in Figure 12 suggests that the North Fork of the Mattole possesses flashy discharge characteristics, and that extremely high or extremely low flows seldom exist for long periods of time. Interpretation of the graph indicates that a stream discharge of 300 cubic feet per second is equalled or exceeded only **16.3** percent of the time.

**FIGURE 12- FLOW DURATION CURVE OF THE  
NORTH FORK OF THE MATTOLE RIVER  
AT PETROLIA, CALIFORNIA**

1952-1957

Minimum Momentary Flow: 2.0 CFS (Sept. 4, 1955)

Maximum Momentary Flow: 9,600 CFS (Dec. 21, 1955)

Semi-Logarithmic  
4 Cycles x 10 to 100 inch

PERCENT OF TIME THAT DISCHARGE IS EQUALLED OR EXCEEDED

Conversely, the graph indicates that stream discharge is less than 7 cubic feet per second only 9.8 percent of the time. A discharge of 40 cubic feet per second is equalled or exceeded 50 percent of the time.

#### Water Use

Aside from domestic use of water obtained from wells in the Petrolia area, small diversions of water are made from the North Fork of the Mattole above Petrolia for irrigation purposes. Approximately 200 acres of land within the watershed receive full irrigation. Another 180 acres in the lower portion of the watershed are used for dry-farming. Figure 9A gives the location of these areas.

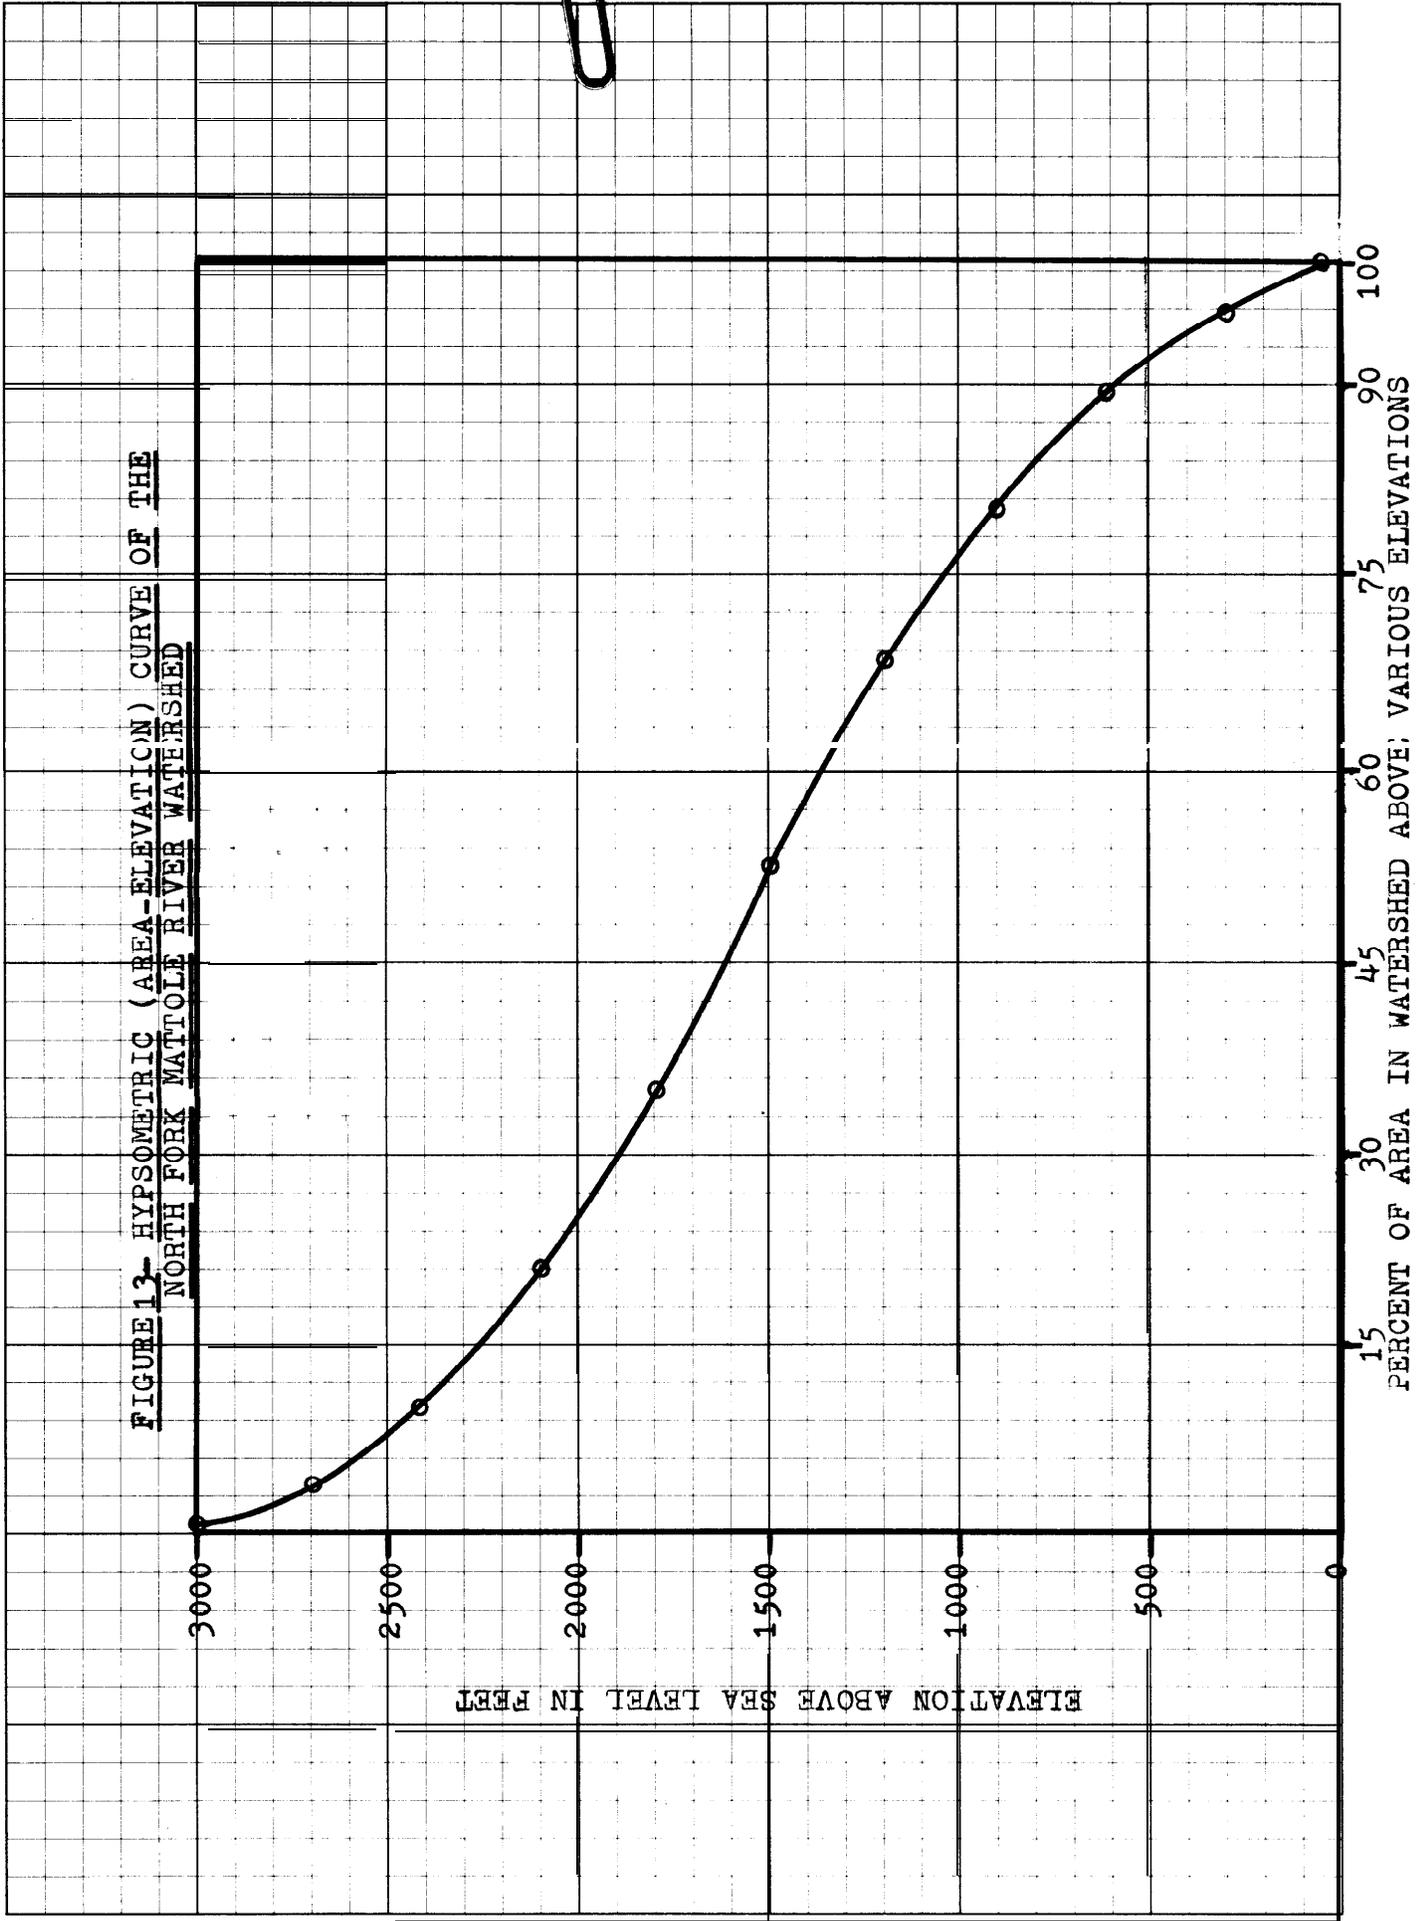

#### HYYSOMETRIC CURVE

A hypsometric (area-elevation) curve has been constructed for the watershed and is displayed in Figure 13. Table C, in the appendix, was used in construction of the curve. This curve provides information on the percent of area in the watershed that is located above (or below) a given elevation. The curve steepens near the top and bottom, and graphical interpretation indicates that only 11.1 percent of the area in the watershed is lower than 600 feet in elevation, and that only 9.5 percent of the watershed area is higher than 2,400 feet.

#### OTHER PHYSIOGRAPWIC PARAMETERS

A number of parameters have been presented in Table 5, some of which are self-explanatory, and others which need to be discussed.

FIGURE 13- HYPSONOMETRIC (AREA-ELEVATION) CURVE OF THE  
NORTH FORK MATTOLE RIVER WATERSHED

### Elevation And Slope

Mean elevation and slope values were obtained by systematically **sampling** 100 points within the watershed, using a grid. Slope was obtained by measuring 1,000 feet from each sample point in the direction of slope, and by counting the number of contour lines crossed, percent slope was obtained. Slope direction indicates the particular aspect at each sample point-, and mean area-aspect relations of the watershed were computed from these tabulations.

The minimum elevation in the watershed is 50 feet where the North Fork empties into the **main** Mattole River. The maximum elevation in the watershed is 3,500 feet, located on a peak in the extreme eastern extension of the watershed (**Fig. 2**). Variations between subdivided basins within the watershed in terms of **minimum**, mean, and maximum elevations are not extreme.

Variation in mean percent slope between the basins within the study area is not extreme, but the East Branch North Fork basin is slightly steeper. Page B, Table 5 also indicates that **steepness** of slope depends upon aspect in each basin. In all basins, nearly 50 percent of the watershed area is represented by south and west aspects. This is important from a hydrologic and erosion standpoint, because it means that nearly 50 percent of the surface area of the watershed is facing in line with the general direction of storm movement in the area. Thus these slopes bear the brunt of the storm forces.

A comparison of slope values on the Soil-Vegetation Map (Fig. 8) with slope values obtained by systematic sampling indicates an underestimation of mean percent slope by the sampling method. Aerial photography (with ground checks) is used to estimate slope percent on the Soil-Vegetation Map, and uncorrected error due to vertical exaggeration of the photos may account for a portion of the discrepancy. However, it is the author's opinion that mean percent slope in each basin exceeds the values in Table 5. A sample size of greater than 100 points might prove this hypothesis.

Additional information on slope for the study area as a whole is provided in Figure 14. This graph shows that 75 percent of the area within the watershed occurs on slopes from 21-40 percent, with 15 percent of the total watershed area in the 41-60 percent slope classes, and 10 percent of the total area in the 0-20 percent slope classes.

#### Basin Relief

This value equals the vertical distance between the mouth of the basin and the highest point in the basin. Values recorded on page C, Table 5 indicate little variation between basins in the study area, thus indicating similar relief throughout the watershed.

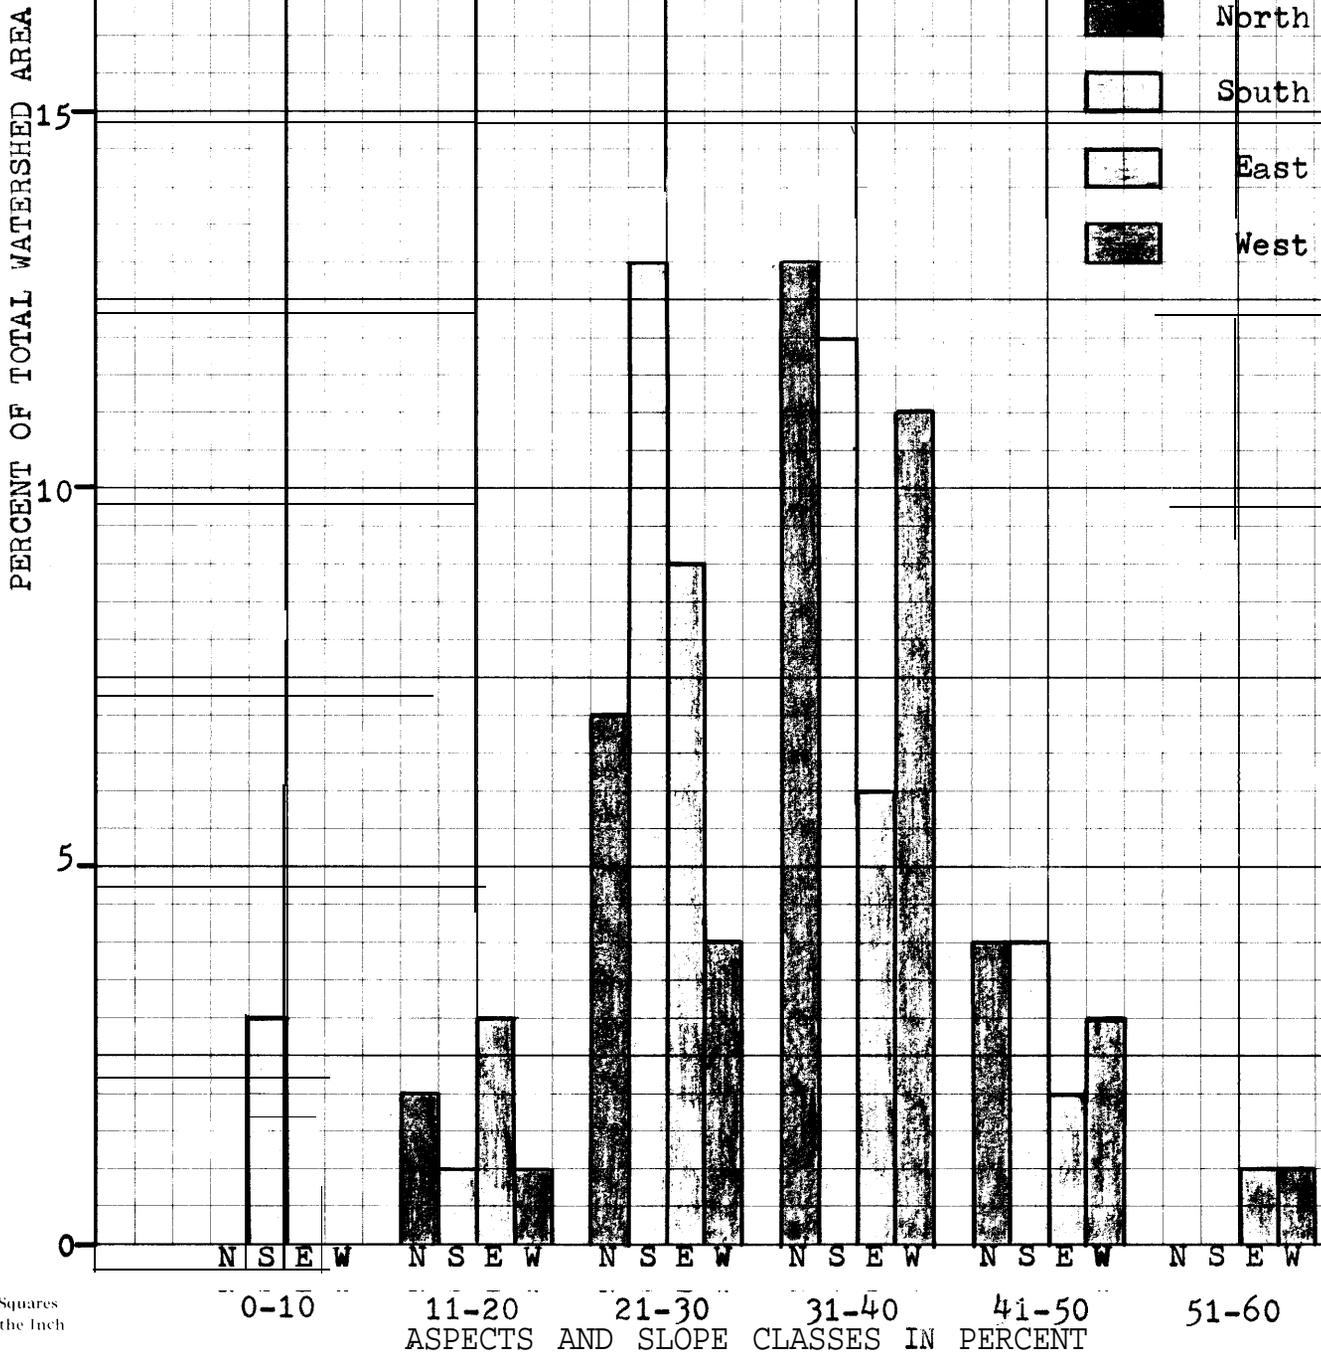

#### Ruggedness Number

This unitless value equals the product of drainage density and basin relief. Similarity in the values for the individual basins indicates general equality of terrain ruggedness throughout the study area.

PART II

SOCIO-ECONOMIC ANALYSIS

Introduction

In discussing the history and the general socio-economic considerations of the watershed, the analysis at times will include important information in reference to the entire **Mattole River** drainage. The occurrence of certain historical and land-use **activities** outside of the **North Fork** watershed may have directly or indirectly affected the study area itself, and for this reason, the report will not be limited to an analysis of the relatively small area represented by the watershed proper.

Early History Of Land Use

Reports indicate that **Indians** were the first reported **inhabitants** of the **Mattole Valley** in the early 1800's and probably earlier. It would be conjecture to evaluate the impact of the nomadic **Indians** on the resources of the area, but with no doubt the intensity of land use in the area today far exceeds the degree of land use or misuse that can be **attributed** to the **Indians**.

The **Mattole Township** was established in 1859, although settlers were living in the **Mattole Valley** as early as 1854 (Community of **Petrolia**, 1962). An event of great importance in the history of **Petrolia** is the arrival of settlers to the area from the farming region of **Marysville**, California, during the period from 1868 to 1876. With them the settlers brought their agrarian ideas, and as a result agricultural development

for commercial purposes and domestic uses ensued. Fruit crops, and **other** crops such as wheat, hay, corn, potatoes, **etc.** were introduced into the area. Livestock (cattle and sheep) began to appear in the Mattole **basin**.

**Not** only did the migration of the **Marysville** settlers influence the population growth and development of Petrolia, as well as the remaining Mattole basin; but the discovery and subsequent **drilling** of the first productive oil well in California occurred within the watershed of the North Fork of the Mattole River in **1861**, and this has had a lasting impact on the area to this date. The 500 foot well was drilled by the Union Mattole Oil Company on the Edmonston Ranch, T. **1S.**, R. **1W.**, Section 30 (**Lytel, 1966**). The town of **petrolia** has **derived its** name from the presence of **oil** in the region.

After the first oil **strike**, the area was subjected to an exciting "**oil boom**" that lasted **until** 1866, and which increased the population of Petrolia from **approximately** 200 inhabitants to "**many hundreds**" of **inhabitants**, temporary and permanent (Community of **Petrolia, 1962**). However, the **oil boom** soon lost its **momentum**, undoubtedly **because** of the following factors that have been offered by Lytel. 1) The relative **inaccessibility** of the **Mattole** region resulted in an expensive and at times impossible transportation of **oil-**extraction equipment to the area, at a cost that could not compete with extraction and transportation of oil to the West from oil fields **in** Pennsylvania. 2) The quantity of the oil resource that was extracted in relation to the

extraction cost resulted in the total enterprise acquiring a reputation of economic **infeasibility** (Lytel, 1966).

In 1865, the Union **Mattole** Oil Company contracted shipments of **oil** to a San Francisco **refinery**, via oceanliner, but the enterprise was short-lived. Additional **and** short-lived **oil booms** occurred in the region in **1889, 1900, 1907, 1921, and** sporadically from 1953 to the present. Numerous drilling sites dot the **Mattole** area, and information **on** the most **recently-**productive well is given in **Table 8**.

During 'the first 35 years of the existence of Petrolia, the livelihood of the area was supported principally by crop raising **with stock raising** as 2nd in importance, and income from timber harvesting as 3rd in importance. The raising of wheat as an important crop continued until fruit and livestock raising began to pass grain production about 1900. In 1921, production of grain for commercial flour **ended** in the Petrolia area (Community of **Petrolia**, 1962).

**Cattle** raising has been an important stock in the area since pioneer times, and remains so today. The raising of sheep in the area increased in popularity as predators became more scarce following the **initial oil boom in the 1860's**.

#### PRESENT LAND USE

Today cattle and sheep raising **constitute** the principle livelihood or occupation of the area, with logging assuming responsibility for the prime source of income to the region (Schwarzkopf, 1949, and Community of Petrolia, 1962). Logging **is** carried on mostly by private contract, but also by many

individual landowners themselves while engaging in **ranching** activities. The intensity of **logging** In the study area within the last five years has already been **mentioned**, and is supported by **the** above as well as by information in Figure 9, Part I. **Oil** speculation In the area **is** nearly at a standstill today. However, **very** recent **reports** indicate that applications have been submitted to the Federal Government concerning leases for exploratory oil drilling purposes **in** the **Mattole** basin, and leases have subsequently been granted to private concerns for certain parcels (Humboldt Standard, 1967).

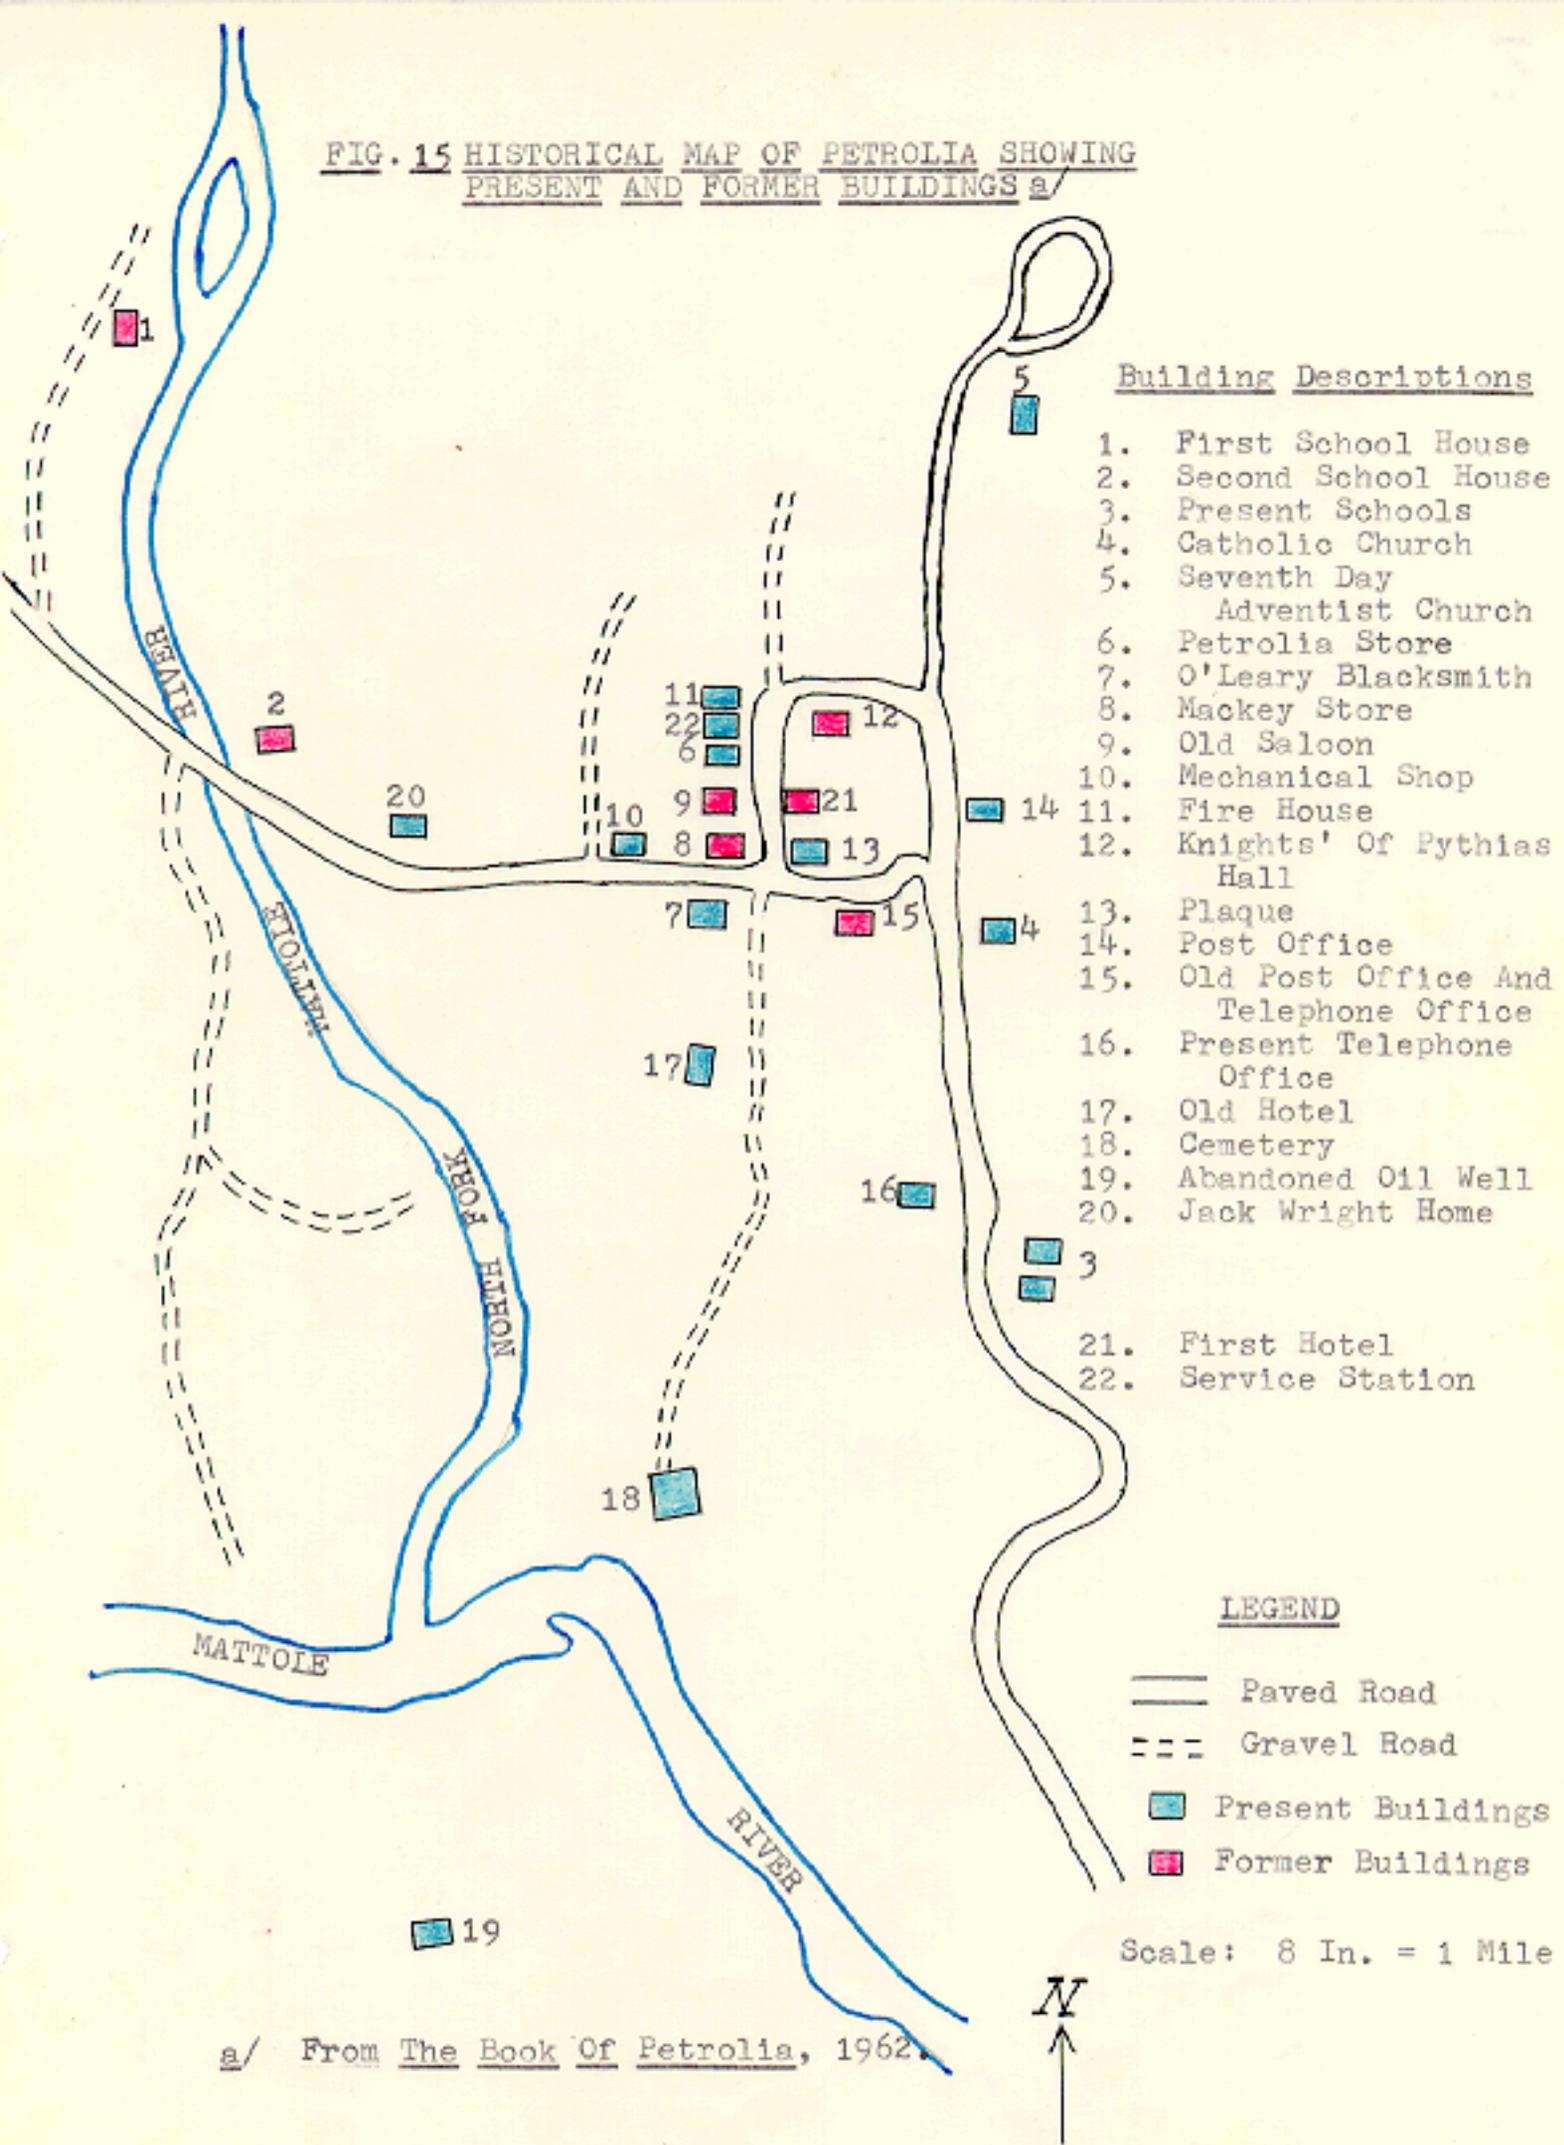

#### PETROLIA TODAY

At present no more than a few dozen residents occupy the town proper. The **1950** Federal census indicated that the population within the Mattole Union School District (**i.e.** **Mattole** basin) did not exceed **200** (Community of Petrolia, 1962). A historical map of Petrolia is displayed in Figure **15**.

Were it not for the several following factors, **Petrolia** might never have grown into any semblance of a permanent town. 1) The hope of striking productive oil deposits **never** died, and hope has not been abandoned to **this** day. 2) New spurts in **agricultural activity** occurred from time to time during and after the **oil boom periods**. **3)** Recently, the **desirability** of the **Mattole** drainage and the surrounding area for recreational purposes has **been** realized.

However, **five** factors have significantly contributed to the decline in population of Petrolia. 1) The collapse of the oil booms. 2) The decline in the **profitability** of

FIG. 15 HISTORICAL MAP OF PETROLIA SHOWING PRESENT AND FORMER BUILDINGS a/

crop raising, especially commercial fruit production.

**3)** The automobile has allowed residents to trade *in distant* communities, thus **eliminating** the need for many shops and services in the Petrolia area. **4)** The consolidation of properties into larger holdings. **5)** Several **calamities** have affected Petrolia: a large fire in the town in **1903**, several earthquakes of great severity, the worst of which was in 1906, and the **1955** flood which destroyed some of the older buildings, as well as **livestock** and low-lying **cropland** (Community of Petrolia, 1962).

#### WATER REQUIREMENTS

Present and future water requirements of the complete **Mattole** basin, which includes the communities of Petrolia, Honeydew, and Thorn, are listed in Table 9. Use requirements indicate that the total annual water supply far exceeds the present and anticipated demand of the commodity for all forms of use. However, **summer flows** are not expected to be sufficient to meet future requirements until storage provisions are made to allow **full** development of water resources along the **Mattole** (U.S. Dept. of the Interior, 1960).

Within the Pacific Basins Group of the California Water Plan, a dam capable of yielding 33,000 acre-feet annually may eventually be built at Thorn near the headwaters of the main **Mattole** River. The proposed yield of the dam greatly exceeds the requirements of the area and the excess waters could be used for fish and **recreation** enhancement. Costs of such a **project** are estimated in excess of **\$7,000,000** (Winzler and

a/ From U.S. Army Corps of Engineers, 1965.

Kelly, 1962).

**Because** the Mattole River has not been victimized by **either** industrial or human pollution, the stream has been chosen by the U.S. Geological Survey for a special study. The study is related to an evaluation of the impact of dissolved **minerals** introduced by stream sediment on water quality. The **relative** purity of the stream from a chemical pollution standpoint allows this relationship to be more easily and **accurately** determined (Kelsey, 1967).

#### RECREATION

##### Fisheries Resource

King and Silver Salmon and Steelhead Trout in the Mattole River support the **principal** recreation activity in the area. King **Salmon** annual runs presently number about **5,000** and Silver **Salmon** about 2,000. Annual runs of about 12,000 Steelhead are also estimated (U.S. Dept. of the Interior, 1960). The Mattole River **is** accessible to King Salmon for about **45 miles**. King Salmon spawn mostly in the **main** river; however, certain tributaries, one of which **is** the North Fork, **provide** suitable **spawning areas**.

Most of the **catch** of **King** Salmon is made in November. During the **1957-1958** seasons an average **4,300** angler-days were spent on the river, resulting in a catch of 400 salmon, 700 steelhead, and about 8,000 juvenile **steelhead** trout (Calif. State **Dept.** of Water Resources, 1965).

### Game Resouroa

Deer Hunting **is** successful in the general area as **Columbian** Black-Tailed Deer (*Odocoileus hemionus columbianus*) has its natural range in the North-Coast area, including the **Mattole drainage**. However, general private ownership of the **Mattole** basin has presented hunting problems when lands have been posted and cooperative relations have not been achieved between hunters and landowners.

Other important game species such as the Northwestern Black Bear (*Euarctos americanus altifrontalis*), California Quail (*Lophortyx californicus*), and Mourning Dove (*Zenaidura macroura*) inhabit the **Mattole area** and offer limited hunting opportunity.

### Improved Recreation Facilities

Improved recreation facilities are **limited** within the **Mattole** basin. A few private concerns provide lodging which is u-gently needed for sportsmen in season. A few private, riverside campgrounds with limited facilities exist along the main branch of the **Mattole**.

### Wilderness Area

Of definite socio-economic significance to the **Mattole** basin is the King Range National Conservation Area. This 31,500 acre wilderness area is administered by the Bureau of **Land** Management and is situated between the **Mattole** River and the Pacific Ocean. The area provides access roads, campgrounds **with** limited facilities, **trails, and** breathtaking scenery from King's Peak, elevation **4,087** feet. Major access to the area

**is provided** via **Petrolia** and Honeydew, and seasonal recreation **activity** In the King's Area Indirectly **stim-**ulates the economy of these **communities** to an important degree,

PART III

GENERAL PROBLEMS

Introduction

In general, the discussion of general problems **within** the watershed **will** be an expansion of facts and ideas that have been previously mentioned. However, a few important factors that have not previously been mentioned will **also** be included in this part of the analysis.

Accessibility

**Even** though access to the watershed **is** provided from various **directions** in Humboldt County, the roads are somewhat hazardous and unreliable at times. Temporary road closures are likely to occur at any time during the winter, as slides and washouts are not uncommon. Additional road paving within the future **will** alleviate this problem.

Access into the watershed itself is **limited** during the winter by the preponderance of dirt roads. The upper portions of the watershed are generally accessible only to four-wheel-drive vehicles during the winter.

Fire'

The study area proper has received a very **minor** impact by wildfire within the last five years. During this period, only three fires have been reported and controlled within the watershed, and all of these have been **small spot** fires related to **logging activities**. The three fires occurred during the **critical** fire summer of **1964** (Calif. Division of Forestry, **1964**).

During this same year, a **wildfire** that started near Petrolia on September **23rd** was carried **southeastward** by the prevailing winds, ultimately consuming 20,000 acres of rugged watershed land located mainly to the west of the **Mattole** River. The fire was halted near the northern boundary of the **King** Range. The northern advancement of the fire was stopped on Apple Tree Ridge, which forms a portion of the southern border of the North Fork **Mattole** River Watershed (Fig. **2, Part I**). Destruction of an undetermined amount of farm acreage and some **structural** losses, as well as watershed losses have been **attributed** to this fire.

#### FLOODS

##### Flood Of 1955

Major damage occurred in the lowlands of the study area as well as along the main branch of the **Mattole** during the **1955** flodd (Community of Petrolia, **1952**). Specific information is **lacking**, but it **is** certain that a number of structures and valuable farmland were **damaged**. Momentary maximum flow on the North Fork of the **Mattole** River at **Petrolia** was recorded as 9,600 cubic feet per second on December 21, **1955**.

##### Flood Of 1964

Early reports indicated that the **Mattole** Valley remained relatively **unscathed** by the unprecedented flood of December **1964** (Humboldt Times, **1964**). These reports were correct from the standpoint of **residential** losses, but a later evaluation of damages by the U.S. Army Corps of **Engineers** revealed that nearly \$1,000,000 **in** losses (Table 10) had been incurred due to

a summation of agricultural, transportation (roads and bridges), and industrial damages within the **Mattole** Valley (U.S. Army Corps of Engineers, 1964). During the flood, the county roads to **Petrolia** were closed and the town was without **electricity**. Bridges crossing the **Mattole** were not washed out, but partial bridge damage was commonplace.

The momentary maximum flow **on** the **North Fork** was not measured during the 1964 flood because of the termination of gaging measurements on the stream in **1957**. However, Figure **16** provides the high water mark levels of the flood, and if stage-discharge relationships are known, the maximum flow can be reliably estimated. As Figure **16** **indicates**, the town of **Petrolia** was not flooded during the **1964** flood.

During the **72-hour** storm period from December **20th** to December **23rd** that preceded the flood, -an average of **17** inches of precipitation fell within the **North Fork Mattole River Watershed** (U.S. Army Corps of Engineers, **1964**). As a result, minor landslides, road washouts, and stream blockages were commonplace throughout the watershed.

#### Erosion And Land Misuse

The previously-mentioned **Mattole** Fault Shear **Zone** presents a natural erosion problem. Figure **6**, (**Part I**) indicates that the shear zone prevails along the apex of an **anticline**, where beds dip downward on an average of **45** degrees from either side of the shear zone. Slippage of the beds near the apex of the **anticline** have created the shear zone. Highly unstable soil conditions have been created in this area, especially where

Figure 16

DECEMBER 1964  
FLOOD PLAIN AND HIGH WATER MARKS

could not be included  
due to its size.

PART IV

POTENTIALS OF THE AREA

Introduction

The biotic and physical resources within the study area that contribute to the economy or to the potential development and use of the **components** within the watershed are discussed in decreasing order of present importance, economic or otherwise.

Timber

Economically, timber harvesting is the most important activity within the study area. This will probably change in the near future because of the **following** factors. 1) A timber site **class** of **III characterizes** the average timber growth **potential** of the watershed (Fig. 8, Part I); meaning that **dominant** and **codominant** timber (primarily Douglas-fir) will achieve a height of 140 feet in 100 years, whereas 200 feet per year is optimum (Site I) growth. 2) Assuming the present rate of timber extraction **continues**, the entire forested portion-of the watershed will be **logged** of 70 percent of the merchantable timber volume In **another 5 to 7** years. 3) Conversion of marginal timberland areas to grassland by means of logging and controlled burning will continue to preclude logging on certain land parcels.

The "average" timber **site** quality of the watershed is primarily a reflection of **edaphic conditions**. The Hugo (812) soil series that covers the majority of the timberland site acclaims only moderate suitability for timber production (Black, 1964).

### Forage

The **Mattole** area has been acclaimed as prime range country because of the abundant rainfall, temperate climate, and fertile soil (Schwarzkopf, 1949). Abundant rainfall and temperate climate are definite attributes of the area. The information in Table 2 (Part I), supports the acclaimed fertility of the soil. The three grassland soils of the lower portion of the watershed, i.e. **Kneeland (852)**, and **Mattole (952)** are classified as being "high" to "very high" in suitability for range use, Only the higher elevation **Wilder (840)** soil is given a low rating for suitability of forage potential. Conversion of certain timber soils to grassland, such as **Usal (818)**, will provide additional rangeland of high quality.

### Crops

Alluvial deposition has created a limited area near Petrolia for raising such crops as corn, potatoes, wheat, hay, etc. Areas directly above **Petrolia** are suitable for growth of orchard crops, especially apples, but the potentiality is limited by the fixed factor of acreage, as the information in Table 4 (Part I) suggests. Potential production of crops in the area for anything other than localized commercial or domestic purposes is negligible.

### Recreation

Recreation offers the greatest potential for future use of the lower portion of the watershed, especially on those lands located near the river. A current seasonal recreation use of the area could develop into an annual endeavor if

population expansion so demands.

**Increased** intensity of hunting and fishing in early Fall and Winter, combined with Increased Spring and **Summer** use In the form of camping, **hiking**, sightseeing, etc., could become a more tangible reality In the area. This **would** require a narrower disparity between logging with only short-term economic **gain** in mind and logging with definite consideration of the public Interest In mind.

The Introduction or **buildup** of certain game species **is** potentially feasible In the watershed. Species such as the Band-Tailed Pigeon (**Columba fasciata**), Mountain Quail (**Oreortyx picta**), and Oregon Sooty Grouse (**Dendragapus fuliginosus**), that find their natural range in this area, might increase in **population** due to habitat improvement by logging and land conversion.

### **Oil**

The likelihood of future productive oil achievements In this region **is** questionable, as it always has been, and as a result the **potential** for development rates low on the priority **list**. The **following** citation from the 37th report of the State **Minerologist** appropriately expresses the possibility of future commercial **production** of Oil In the

### **Mattole region:**

The widespread **dips** and **faults** In the Mattole and Bear River districts are not regarded as favorable for the **accumulation** of large bodies of Oil. The results- that have **been obtained** by some of the wells In this **district** indicate that oil and gas are locally trapped and prevented from escape along the vertical or nearly vertical strata. Exposed structural conditions near some of the most encouraging wells,

especially that of the North Counties Oil Co., strongly suggest that at least some of these accumulations of oil and gas are in localities that have been broken by a system of faults. It seems probable that **these** faults have combined to produce suitable **conditions** for the accumulation and retention of oil and gas locally, but it **is** uncertain that such local deposits, when tapped by the drill, will yield oil and gas in commercial quantities. In view of the encouraging results obtained by some wells, the district may produce small quantities of oil and gas for a considerable period. However, owing to the structural conditions, even if **production** is obtained in one well, each subsequent well drilled must be considered a wildcat well with much chance of failure.

(Averill, 1928).

PART V

RESOURCES SUMMARY

Introduction

This resource summary specifically **lists** only those resources that are found within the North Fork **Mattole** River Watershed.

Land Resource

The North Fork Mattole River **Watershed** contains **24,064** acres of land, of which **13,765** acres are in the North Fork basin and 10,299 acres are in the East Branch of the North Fork basin.

Timber Resource

Commercial timber (primarily Douglas-fir) is found on **6,630** acres within the watershed. Of this, only 2,850 acres supports **old-growth** timber, and the remaining 3,780 acres supports **2nd-growth** timber. In addition, 1,300 **acres** of the watershed supports a hardwood vegetative cover, consisting primarily of **Tanoak** and **Madrone** in that order of density.

Range Resource

The study area includes 8,220 acres of grassland, of which **6,930** acres offers prime grazing land for livestock such as **Romney** and Suffolk Sheep, and cattle. The other **1,290** acres of grassland is better suited for forest management uses.

### Cropland Resource

Fertile, **irrigable** croplands comprise 1,004 acres within the watershed, of which **540** acres are smooth-lying. At present only 200 acres within the watershed are **receiving** full. **irrigation**, and another **180** acres are being used for dry-farming. The fertility of **the cropland** as well as the general **climate** of the area **is compatable** with production of such crops as hay, corn, wheat, potatoes, beans, and other garden crops. **Fruit** crops, such as apples, pears, plums, and berries are found within the **area**.

### RECREATION RESOURCES

#### Fisheries Resource

King and Silver Salmon, as well as Steelhead Trout are found **within** the watershed in undetermined but significant numbers as a result of annual migration runs that occur along the main branch of the Mattole River. There are indications that the fisheries resource has recently depreciated in value due to an Increase in **stream** turbidity and stream obstructions, caused by specific land misuse as well as by natural geologic problems within the area.

#### Game Resource

Black-tailed deer abound in the watershed. Other game species, such as Black Bear, California Quail, Mourning Dove, **Black-tailed** Jackrabbit (**Lepus californicus**), and **Douglas** Squirrel (**Tamiasciurus douglasii**), find their natural range within the area, and offer limited hunting.

Water Resource

The North Fork **Mattole** River drainage network Includes **46.7 miles** of perennial streams. Mean annual runoff from the watershed is 128,543 acre-feet, the **yield** from a mean annual basin-wide precipitation of 73.0 inches less the water losses through **evapo-transpiration** and soil-water retention.

PART VI

CONCLUSIONS

General

The land area discussed In **this** report has been subjected to an Intensive impact by man, primarily during the oil boom of the 1860's and during the last five years as a result of logging and range activities. During the last **25** yrs, as well as today, recreation **activity remains as** a definite **asset** to the area. However, the future of the recreation **resource, which** Is **primarily** based upon the fisheries and game resources of the area, **will** depend to a large degree on the future timber and range activities of the area, and possibly upon oil extraction activity.

Erosion And Land Misuse

Ownership within the watershed Is broken into numerous parcels. Thus, each land owner possesses varying land-use objectives and **practices**. **Logging** and land conversion activities In the watershed are regulated by the California State Forest Yractfce Acts. However, the **ambiguity** of phraseology that **is** inherent In the composition of the Forest Practice Acts, places undeniable llmltatlons on the degree of enforceability of the **same**, by the California Division of Forestry. The effectiveness of constructive **criticism** regarding private logging practices by sincere conservationists and recreationlsts Is often nullified by the mere existence of the Forest Practice Acts, which are dogmatically lauded by private owners with seldom **mention** or apparent **realization**

of their limitations. It is easier for owners of small parcels to "get away" with poor logging practices, overgrazing, etc. Land misuse on large holdings is more likely to be detected and corrective measures demanded, either by public agencies or an irate public.

In spite of the above limitations, corrective or preventative measures can be applied in the watershed. It should be emphasized though, that certain natural characteristics of the area, such as those geologic factors previously discussed, intense rainfall, and steep slopes contribute significantly to the problems of erosion and stream sedimentation.

Landowners should strive to avoid site disturbance on the Atwell soil series in the watershed. Areas colored dark red on the Soil Vegetation map should be avoided, especially in reference to future road location.

When possible, sheep should be replaced with cattle in the watershed, especially on the steeper grassland slopes. Sheep are noted for cropping off the grass shorter than cattle, and because of this their presence offers more of a risk in terms of erosion inducing potential.

### Future

Improved access to the area may create an increase in recreational demand for the watershed. An extension of State Highway 1, north from its termination point in Fort Bragg, Mendocino County, would provide the impetus for increased recreation activities.
